Abstract

Let $A_k, k \in \mathbb{N}$ be a sequence of $n \times n$ complex valued matrices which converge to a matrix $A$. If $A$ and each $A_k$ is positive then the product

$$\frac{A_kA_{k-1}...A_2A_1}{||A_kA_{k-1}...A_2A_1||}$$

converges to a rank one matrix positive matrix $uw^T$, where $u$ is a positive column eigenvector of $A$. If each $A_k$ is nonsingular and $A$ has exactly one simple eigenvalue $\lambda$ of the maximal modulus with the corresponding eigenvector $u$, then $e^{\frac{1}{\theta_k}||A_kA_{k-1}...A_2A_1}{||A_kA_{k-1}...A_2A_1||}$, $\theta_k \in \mathbb{R}$ converges to a rank one matrix $uw^T$.

2000 Mathematical Subject Classification: 15A48, 47H09, 65L20

Keywords: Positive matrices, contractions, convergence of products of matrices, projective spaces.

1 Introduction

For $F = \mathbb{R}, \mathbb{C}$ denote by $F^n, M_n(F), GL_n(F)$ the $n$-dimensional column vector space, the algebra of $n \times n$ matrices and the subgroup of $n \times n$ invertible matrices over the field $F$. Denote by $|| \cdot ||$ any vector norm on $F^n$ or on $M_n(F)$. Let $|| \cdot ||_2$ be the $\ell_2$
norm on $\mathbb{F}^n$ induced by the standard inner product $\langle x, y \rangle := y^*x$ on $\mathbb{F}^n$ and denote by $\| \cdot \|_2$ the induced operator norm on $M_n(\mathbb{F})$. Consider an iteration scheme

$$x_k := A_k x_{k-1}, \quad x_0 \in \mathbb{F}^n, \ A_k \in M_n(\mathbb{F}), k \in \mathbb{N}.$$  \hspace{1cm} (1.1)

This system is called convergent if $x_k, k \in \mathbb{N}$ is a convergent sequence for each $x_0 \in \mathbb{F}^n$. This is equivalent to the convergence of the infinite product $\ldots A_k A_{k-1} \ldots A_2 A_1$, which is defined as the limit of $A_k A_{k-1} \ldots A_2 A_1$ as $k \to \infty$. For the stationary case $A_k = A, k \in \mathbb{N}$ the necessary and sufficient conditions for convergence are well known. First, the spectral radius $\rho(A)$ can not exceed 1. Second, if $\rho(A) = 1$, then 1 is an eigenvalue of $A$ and all its Jordan blocks have size 1. Third all other eigenvalues $\lambda$ of $A$ different from 1 satisfy $|\lambda| < 1$.

In some instances, as Lyapunov exponents in dynamical systems [11], one interested if the line spanned by the vector $x_i$ converges for all $x_0 \neq 0$ in some homogeneous open Zariski set in $\mathbb{F}^n$ [2]. If this condition holds we call (1.1) projectively convergent.

For the stationary case $0 \neq A_k = A \in M_n(\mathbb{C})$ it is straightforward to show that (1.1) is projectively convergent if and only if among all the eigenvalues $\lambda$ of $A$ satisfying $|\lambda| = \rho(A)$, there is exactly one eigenvalue $\lambda_0$ which has Jordan blocks of the maximal size. See for example the arguments in [4, Thm 2.2].

A variation of projectively convergent iterations was considered in the literature for the nonnegative matrices under the name nonhomogeneous matrix products [7], [12] and [8]. Let $\mathbb{R}_+ := (0, \infty)$ and denote by $\mathbb{R}_+^n \subset \mathbb{R}^n, M_n(\mathbb{R}_+) \subset M_n(\mathbb{R})$ the cone of positive vectors and the semialgebra of positive matrices. Denote by $\mathbb{P} \mathbb{R}^n_+$ and $\mathbb{P} M_n(\mathbb{R}_+)$ the projective space formed by the rays spanned by $x \in \mathbb{R}_+^n$ and $A \in M_n(\mathbb{R}_+)$. Then $\mathbb{P} \mathbb{R}^n_+$ has the Hilbert (hyperbolic) metric. Furthermore each $A \in M_n(\mathbb{R}_+)$ acts on $\mathbb{P} \mathbb{R}^n_+$, where this action is denoted $\hat{A} : \mathbb{P} \mathbb{R}^n_+ \to \mathbb{P} \mathbb{R}^n_+$, and $\hat{A}$ is a contraction [1]. That is the Lipschitz constant $L(\hat{A})$ of $\hat{A}$ is less than 1. Let $A_k \in M_n(\mathbb{R}_+), k \in \mathbb{N}$ be a sequence of positive matrices. Then the condition $\lim_{k \to \infty} L(\hat{A}_1 \ldots \hat{A}_k) = 0$, which is equivalent to the notion of weak ergodicity of the products $A_1 \ldots A_k, k \in \mathbb{N}$ [12], implies that for each $x_0 \in \mathbb{R}_+^n$ the ray spanned by $A_1 \ldots A_k x_0$ converges to a fixed ray in $\mathbb{P} \mathbb{R}^n_+$.

Clearly $A_k \ldots A_1, \in M_n(\mathbb{R}_+), k \in \mathbb{N}$ is projectively convergent if

$$\lim_{k \to \infty} \frac{A_k A_{k-1} \ldots A_2 A_1}{\|A_k A_{k-1} \ldots A_2 A_1\|} = E, \quad \text{where} \quad \|E\| = 1$$  \hspace{1cm} (1.2)

and $E \in M_n(\mathbb{R}_+)$. We show that the assumption

$$\lim_{k \to \infty} L(\overline{A_k \ldots A_1}) = 0 \quad (\iff \lim_{k \to \infty} L(\overline{A_1^T \ldots A_k^T}) = 0)$$  \hspace{1cm} (1.3)
does not imply (1.2).

The aim of this paper is to show

**Theorem 1.1** Let $A_k \in M_n(\mathbb{R}^+), k \in \mathbb{N}$ be a sequence of positive matrices which converges to a positive matrix $A \in M_n(\mathbb{R}^+)$. Then (1.2) holds. Furthermore

$$E = uw^T, \quad u, w \in \mathbb{R}_+^n, \quad Au = \rho(A)u.$$ (1.4)

One can view the above Theorem as an improvement of [12, Thm 3.6].

**Theorem 1.2** ¹ Let $A_k \in \text{GL}_n(\mathbb{C}), k \in \mathbb{N}$ be a sequence of matrices which converges to a matrix $0 \neq A \in M_n(\mathbb{C})$. Assume furthermore that $\rho(A) > 0$ and the circle $\{z : \in \mathbb{C}, \ |z| = \rho(A)\}$ contains exactly one eigenvalue $\lambda$ of $A$, which is a simple root of its characteristic polynomial. Let $Au = \lambda u, 0 \neq u \in \mathbb{C}^n$. Then the complex line spanned by $A_k \ldots A_1 \in M_n(\mathbb{C})$ converges to the complex line spanned by $uw^T \in M_n(\mathbb{C})$, for some $0 \neq w \in \mathbb{C}^n$. Hence for each $x_0 \in \mathbb{C}^n$ such that $w^Tx_0 \neq 0$, the complex line spanned by $x_k$ given by (1.1) converges to the complex line spanned by $u$.

We now list briefly the contents of the paper. In §2 we recall basic results on the real and complex projective spaces used in this paper. In §3 we discuss Lipschitz continuous maps and contractions, and simple conditions for pointwise convergence of the products of Lipschitzian maps to a constant map. In §4 we prove Theorem 1.1 and use it to prove Theorem 1.2 in the real case. In §5 we prove Theorem 1.2 in the complex case by using directly the results of §3 and Theorem 1.2 in the real case. In §6 we extend Theorem 1.1 to strictly totally positive matrices (of order $p$). We also extend Theorem 1.2 to the case where the limit matrix $A$, has $p$ simple eigenvalues $\lambda_1, ..., \lambda_p$, such that $|\lambda_1| > ... > |\lambda_p| > 0$ and all other eigenvalues of $A$ lie in $|z| < |\lambda_p|$.

## 2 Projective spaces

In this section we recall the well known notions and results about projective spaces used here. Recall that for $F = \mathbb{R}, \mathbb{C}$ the spaces $\mathbb{P}^n, \mathbb{P}M_n(F), \mathbb{P}GL_n(F)$ are obtained by identifying the orbits of the action of $\mathbb{F}^* := \mathbb{F}\backslash\{0\}$ on the nonzero elements of the corresponding sets. (F* acts by multiplication.) Then $\mathbb{P}^n, \mathbb{P}M_n(\mathbb{R})$ and $\mathbb{P}^n, \mathbb{P}M_n(\mathbb{C})$ are compact real and complex manifolds respectively. (For the reason that will be seen later our notation for $\mathbb{P}^n$ is slightly different from the standard notation.) Note that we can view $\mathbb{P}M_n(F)$ as isomorphic to $\mathbb{F}^{n^2}$. For any $U \subset \mathbb{F}^n$

¹Acknowledgement A variant of this theorem was suggested by Boris Shapiro.
we denote by $U \subset \mathbb{P} \mathbb{F}^n$ the set generated by the orbits of $\mathbb{F}^n(U \setminus \{0\})$. \((\{0\} = 0.)\) A set $V \subset \mathbb{P} \mathbb{F}^n$ is called a (projective) variety if $V = \bar{U}$, where $U$ is the zero set of a finite number of homogeneous polynomials over $\mathbb{F}$ in $\mathbb{F}^n$. $H \subset \mathbb{P} \mathbb{F}^n$ is called a hyperplane if $H = \bar{U}$, where $U$ is a subspace of $\mathbb{F}^n$ of codimension 1. $V \subset \mathbb{P} \mathbb{F}^n$ is called a linear space if it is an intersection of a finite number of hyperplanes.

$W \subset \mathbb{F}^n$ is called Zariski open if $W = \mathbb{F}^n \setminus V$ for some variety $V$.

For $x \in \mathbb{F}^n \setminus \{0\}, A \in M_n(\mathbb{F}) \setminus \{0\}$ denote by $\hat{x}, \hat{A}$ the corresponding elements of $\mathbb{P} \mathbb{F}^n, PM_n(\mathbb{F})$ respectively. Let $A \in GL_n(\mathbb{F})$. Then $A$ acts on $\mathbb{F}^n \setminus \{0\}$, so $\hat{A}x = \hat{A}\hat{x}$ for any $x \in \mathbb{F}^n \setminus \{0\}$. That is $\hat{A}$ acts on $\mathbb{P} \mathbb{F}^n$. Let $A \in M_n(\mathbb{F}) \setminus \{0\}$ Then $\hat{A}$ acts on Zariski open set $\mathbb{P} \mathbb{F}^n \setminus \ker\hat{A}$.

Since $\mathbb{P} \mathbb{F}^n, PM_n(\mathbb{F})$ are compact for any sequences $x_k \in \mathbb{F}^n \setminus \{0\}, A_k, B_k \in M_n(\mathbb{F}) \setminus \{0\}, k \in \mathbb{N}$

we can find a subsequence $k_l, l \in \mathbb{N}$ and corresponding $x \in \mathbb{F}^n \setminus \{0\}, A, B \in M_n(\mathbb{F}) \setminus \{0\}$, depending on $k_l, l \in \mathbb{N}$ such that

$$\lim_{l \to \infty} \hat{x}_{k_l} = \hat{x}, \quad \lim_{l \to \infty} \hat{A}_{k_l} = \hat{A}, \quad \lim_{l \to \infty} \hat{B}_{k_l} = \hat{B}.$$ 

Note also

$$\lim_{l \to \infty} \hat{A}_{k_l}x_{k_l} = \hat{A}\hat{x} = \hat{A}\hat{x} \quad \text{if} \quad Ax \neq 0,$$

$$\lim_{l \to \infty} \hat{A}_{k_l}B_{k_l} = \hat{A}\hat{B} = \hat{A}\hat{B} \quad \text{if} \quad AB \neq 0.$$ 

The convergence of sequences in $\mathbb{P} \mathbb{F}^n$ and $PM_n(\mathbb{F})$ are equivalent to the following statement:

**Proposition 2.1** Let $x_k \in \mathbb{F}^n \setminus \{0\}, A_k \in M_n(\mathbb{F}) \setminus \{0\}, k \in \mathbb{N}$. Then sequences $x_k, A_k, k \in \mathbb{N}$ converge in $\mathbb{P} \mathbb{F}^n, PM_n(\mathbb{F})$ respectively if and only if there exist two sequences $\mu_k, \nu_k \in \{z \in C : |z| = 1\} \cap \mathbb{F}, k \in \mathbb{N}$ such that the sequences $\mu_k \frac{x_k}{||x_k||}, \nu_k \frac{A_k}{||A_k||}, k \in \mathbb{N}$ converge in $\mathbb{F}^n, M_n(\mathbb{F})$ respectively.

Note that for $\mathbb{F} = \mathbb{R}, \mu_k, \nu_k \in \{1, -1\}$. Thus if $x_k \in \mathbb{R}^n_+, A_k \in M_n(\mathbb{R}_+)$ it is clear that in Proposition 2.1 we may assume that $\mu_k = \nu_k = 1$. Hence for $A_k \in M_n(\mathbb{R}_+), k \in \mathbb{N}$, $\mu_k \frac{A_k}{||A_k||}$ converges in $PM_n(\mathbb{R})$ if and only if (1.2) holds.

Let $\mathbb{P} \mathbb{R}^n_+, PM_n(\mathbb{R}_+)(\approx \mathbb{P} \mathbb{R}^n_+)$ be the set of orbits in $\mathbb{R}^n_+, M_n(\mathbb{R}_+)$ under the action of $\mathbb{R}_+$ (by multiplication). We view $\mathbb{P} \mathbb{R}^n_+, PM_n(\mathbb{R}_+)$ as corresponding subsets of $\mathbb{P} \mathbb{F}^n, PM_n(\mathbb{F})$ respectively. Note that $PM_n(\mathbb{R}_+)$ acts on $\mathbb{P} \mathbb{R}^n_+$. Sometime it is convenient to identify $\mathbb{P} \mathbb{R}^n_+$ and $PM_n(\mathbb{R}_+)$ with the open set of positive probability
vectors and the open set of positive matrices whose sum of coordinates is equal to 1 respectively.

Recall the notion of Hilbert (hyperbolic) metric on $\mathbb{PR}^n_+$ [9], which is not equivalent to the metric induced by the standard Riemannian metric on the compact manifold $\mathbb{PR}^n$. Let

$$d(\hat{x}, \hat{y}) = \log \frac{\max_i \frac{x_i}{y_i}}{\min_i \frac{x_i}{y_i}}, \quad x = (x_1, \ldots, x_n)^T, \quad y = (y_1, \ldots, y_n)^T \in \mathbb{R}^n_+.$$  \hspace{1cm} (2.1)

It is straightforward to show that $d(\cdot, \cdot)$ is a metric on $\mathbb{PR}^n_+$, $\mathbb{PR}^n_+$ is a complete separable metric space with respect to $d(\cdot, \cdot)$, which has an infinite diameter. Moreover, $Y \subset \mathbb{PR}^n_+$ is compact with respect to the above metric if and only if $Y$ is compact with respect to the standard metric on $\mathbb{PR}^n$.

3 Convergence of contractions

Let $\mathcal{X}$ be a complete metric space with the metric $d(\cdot, \cdot)$. For $T : \mathcal{X} \to \mathcal{X}$ let

$$L(T) := \sup_{x \neq y \in \mathcal{X}} \frac{d(Tx, Ty)}{d(x, y)} \in [0, \infty].$$

We assume here that $a \cdot \infty = \infty \cdot a = \infty$ for any $a \in \mathbb{R}_+$ and $0 \cdot \infty = \infty \cdot 0 = 0$. Note that $L(T) = 0$ if and only if $T$ is a constant operator. For any $T, Q : \mathcal{X} \to \mathcal{X}$, $L(TQ) \leq L(T)L(Q)$. $T$ is called Lipschitz continuous if $L(T) < \infty$. $T$ is called a contraction if $L(T) < 1$. Assume that $T$ is a contraction. Then it is well known that $T$ has a unique fixed point $\xi$. Furthermore the sequence $T^i, i \in \mathbb{N}$ converges pointwise to a constant operator $Q : \mathcal{X} \to \{\xi\}$. That is $T^ix \to \xi$ for any $x \in \mathcal{X}$.

**Lemma 3.1** Let $T_i, i \in \mathbb{N}$ be a sequence of operators on a complete metric space $\mathcal{X}$. Let $Q_i := T_1T_2\ldots T_i, i \in \mathbb{N}$ be a sequence of operators. Assume that the following two conditions hold:

$$\lim_{i \to \infty} L(Q_i) = 0.$$  \hspace{1cm} (3.1)

$$\lim_{i \to \infty} \sup_{j \in \mathbb{N}} L(Q_i)d(T_{i+1}\ldots T_{i+j}x, x) = 0, \quad \text{for some } x \in \mathcal{X}.$$  \hspace{1cm} (3.2)

Then $Q_i, i \in \mathbb{N}$ converges pointwise to a constant operator $Q : \mathcal{X} \to \{\xi\}$ for some $\xi \in \mathcal{X}$.  

5
Proof. Since
\[
d(Q_{i+j}x, Q_ix) = d(Q_i(T_{i+1}...T_{i+j}x), Q_ix) \leq L(Q_i)d(T_{i+1}...T_{i+j}x, x) \\
\sup_{k \in \mathbb{N}} L(Q_i)d(T_{i+1}...T_{i+k}x, x)
\]
the condition (3.2) implies that \(Q_ix, i \in \mathbb{N}\) is a Cauchy sequence. Hence \(\lim_{i \to \infty} Q_ix = \xi\). Clearly
\[
d(Q_iy, \xi) \leq d(Q_iy, Q_ix) + d(Q_ix, \xi) \leq L(Q_i)d(x, y) + d(Q_ix, \xi). \tag{3.3}
\]
The condition (3.1) implies the lemma. \(\square\)

Recall that a metric spaces \(\mathcal{X}\) has a finite diameter if \(\sup_{x,y \in \mathcal{X}} d(x, y) < \infty\). Clearly any compact metric space has a finite diameter. Note that if \(\mathcal{X}\) is has a finite diameter then (3.1) implies (3.2).

Corollary 3.2 Let \(T_i, i \in \mathbb{N}\) be a sequence of operators on a complete metric space \(\mathcal{X}\) of finite diameter. Let \(Q_i := T_1T_2...T_i, i \in \mathbb{N}\) be a sequence of operators. Assume that the condition (3.1) holds. Then \(Q_i, i \in \mathbb{N}\) converges pointwise to a constant operator \(Q : \mathcal{X} \to \{\xi\}\) for some \(\xi \in \mathcal{X}\). In particular, if \(T_i, i \in \mathbb{N}\) is a sequence of uniform contractions, i.e. \(L(T_i) \leq a < 1\) for all \(i \in \mathbb{N}\), on a complete metric space \(\mathcal{X}\) of finite diameter then (3.1) holds.

\(A = (a_{ij})^n_{i=1} \in M_n(\mathbb{R})\) is called a nonnegative matrix if \(a_{ij} \geq 0, i, j = 1, ..., n\). \(A\) is called row allowable (column allowable) if \(A\) is nonnegative and \(AR^n_+ \subset \mathbb{R}^n_+\), (\(A^T\mathbb{R}^n_+ \subset \mathbb{R}^n_+)\), i.e. each row (column) of \(A\) contains a positive element. \(A\) is called primitive if \(A\) is nonnegative and there is \(m \in \mathbb{N}\) such that \(A^m \in M_n(\mathbb{R}_+)\). From here and to the end of this section we assume that \(A\) is row allowable unless stated otherwise. Then \(A\) acts on \(\mathbb{R}^n_+\), i.e. \(A : \mathbb{R}^n_+ \to \mathbb{R}^n_+\). It is known that \(A\) is Lipschitz continuous and \(L(A) \leq 1\) \([7]\). It was shown by Birkhoff \([1]\) that for \(A \in M_n(\mathbb{R}_+)\) \(A\) is a contraction. It is known \([12]\) that
\[
L(A) = \frac{1 - \sqrt{\psi(A)}}{1 + \sqrt{\psi(A)}}, \quad \psi(A) := \min_{i,j,k,l \in [1,n]} a_{ik}a_{jl} a_{i\ell}a_{jk}, \quad A = (a_{ij})^n_{i=1} \in M_n(\mathbb{R}_+). \tag{3.4}
\]
For a row allowable nonpositive \(A\) \(\psi(A) = 0 \iff L(A) = 1\). (For a nonnegative non row allowable \(A\) we let \(\psi(A) = -1 \iff L(A) = \infty\).) Note that \(L(A) = 0\) if and only if \(A\) is a positive rank one matrix. Thus \(L(A) = 0 \iff L(A^T) = 0\). Furthermore if \(A_k, k \in \mathbb{N}\) is a sequence of row allowable matrices then the equivalence of the two conditions stated in (1.3) holds.
Let \( A_k = (a_{ij,k})_{i,j}^n, B_k = (b_{ij,k})_{i,j=1}^n \in M_n(\mathbb{R}_+) \) for \( k = N, N+1, \ldots \) and some \( N \in \mathbb{N} \). We say that \( A_k, B_k, k \in \mathbb{N} \) are **asymptotically equal**, and denote it by \( \{A_k\} \sim \{B_k\} \), if
\[
\lim_{k \to \infty} \frac{a_{ij,k}}{b_{ij,k}} = 1, \quad \text{for } i, j = 1, \ldots, n.
\]

The following result is known, e.g. [7].

**Lemma 3.3** Let \( A_k, k \in \mathbb{N} \) be a sequence of nonnegative row allowable matrices. Then \( \lim_{k \to \infty} L(A_k) = 0 \) if and only if there exists a sequence of positive rank one matrices \( B_k \in M_n(\mathbb{R}_+), k \in \mathbb{N} \) such that \( \{A_k\} \sim \{B_k\} \).

**Theorem 3.4** Let \( A_k \in M_n(\mathbb{R}), k \in \mathbb{N} \) be a sequence of nonnegative row (column) allowable matrices. Then \( \lim_{k \to \infty} L(A_1 \ldots A_k) = 0 \) (\( \lim_{k \to \infty} L(A_k^T \ldots A_1^T) = 0 \)) if and only if there exists \( u \in \mathbb{R}_+^n, v_k \in \mathbb{R}_+^n, k \) for \( k > N \) such that \( \{A_1 \ldots A_k\} \sim \{uv_k^T\} \) \( (\{A_1^T \ldots A_k^T\} \sim \{v_ku^T\}) \).

**Proof.** Lemma 3.3 implies that if \( \{A_1 \ldots A_k\} \sim \{uv_k^T\} \), where \( u, v_k \in \mathbb{R}_+^n \), then \( \lim_{k \to \infty} L(A_1 \ldots A_k) = 0 \). Assume that \( A_k, k \in \mathbb{N} \) are row-allowable and \( \lim_{k \to \infty} L(A_1 \ldots A_k) = 0 \). Hence there exists \( k \in \mathbb{N} \) such that \( Q_k = (q_{ij,k})_{i,j=1}^n = A_1 \ldots A_k \in M_n(\mathbb{R}_+) \) for \( k > N \). Then [7, Thm 1] implies that \( Q_k, k \in \mathbb{N} \) tends to row proportionality. That is there exists \( U = (s_{ij}) \in M_n(\mathbb{R}_+) \) such that
\[
\lim_{k \to \infty} \frac{q_{ij,k}}{q_{il,k}} = u_{ij}, \quad i, j \text{ and } i, j = 1, \ldots, n.
\]

Clearly \( u_{ii} = 1 \) and \( u_{ij} = 1 / u_{ji} \). As \( \frac{q_{ij,k}}{q_{il,k}} = \frac{q_{il,k}}{q_{im,k}} \frac{q_{im,k}}{q_{lj,k}} \) it follows that \( u_{ij} = u_{im}u_{mj} \). Hence \( u_{ij} = u_{i1}u_{1j} = u_{i1} / u_{1j} \). Let
\[
u = (u_1, u_2, \ldots, u_n)^T := (u_{11}, u_{21}, \ldots, u_{n1})^T, \quad v_k = (q_{11,k}, q_{12,k}, \ldots, q_{1n,k})^T
\]
and the theorem follows. \( \square \)

**Corollary 3.5** Let \( A_k \in M_n(\mathbb{R}), k \in \mathbb{N} \) be a sequence of nonnegative row allowable matrices. Assume that \( \lim_{k \to \infty} L(A_1 \ldots A_k) = 0 \). Then \( A_1 \ldots A_k : \mathbb{P}\mathbb{R}_+^n \to \mathbb{P}\mathbb{R}_+^n \) converges to a constant operator \( Q : \mathbb{P}\mathbb{R}_+^n \to \{\hat{u}\} \) for some \( u \in \mathbb{R}_+^n \).

Since \( \mathbb{P}\mathbb{R}_+^n \) is not compact under the hyperbolic metric it follows that Corollary 3.5 is a stronger version of Lemma 3.1. We now give an example which shows that the
To prove Theorems 1.1 and 1.2 we use the following well known fact:

**Proof of Theorem 1.1 and Theorem 1.2 for** $R$

To prove Theorems 1.1 and 1.2 we use the following well known fact:

**Proposition 4.1** Let $X$ be a compact metric space. Then a sequence $x_k \in X$, $k \in \mathbb{N}$ converges to $\xi$ if and only if from any convergent subsequence $x_{k_i}$, $i \in \mathbb{N}$ there exists a subsequence $x_{j_k}$, $j \in \mathbb{N}$ which converges to $\xi$.

**Proof of Theorem 1.1.** From the definition of $\psi(A^T)$ in (3.4) it follows that $\lim_{k \to \infty} \psi(A_k^T) = \psi(A^T) \in (0,1)$. Hence $L(A_1^T \cdots A_k^T) \leq L(A_1^T \cdots A_1^T) \to 0$. Theorem 3.4 yields the existence of $w, x_k \in \mathbb{R}_+^n$ such that $\{A_1^T \cdots A_k^T\} \sim \{wx_k^T\}$. Hence $\{A_k \cdots A_1\} \sim \{x_k w^T\}$. 

Corollary 5.2 gives a family of examples for which Theorem 3.6 applies.

**Theorem 3.6** Let $X \subset \mathbb{P}^n$ be a compact set with respect to the Fubini-Study metric $d$ on $X$ and assume that $X$ has a nonempty interior. Let $B_k \in M_n(C)$, $k \in \mathbb{N}$ be a sequence of matrices such that $\overline{\ker B_k} \cap \chi = \emptyset$ and $T_k := B_k : \chi \to \chi$ for each $k \in \mathbb{N}$. Let $Q_k := T_1 \cdots T_k$, $k \in \mathbb{N}$. Assume that $\lim_{k \to \infty} L(Q_k) = 0$. Then $Q_k$ converges pointwise to a constant operator $Q : \chi \to \{\tilde{w}\}$ for some $\tilde{w} \in \chi$. Furthermore the limit of any convergent subsequence $\lim_{l \to \infty} B_{1 \cdots B_l} = \tilde{C} \in \mathbb{P}M_n(C)$ is of the form $\tilde{w} z^T$, where $z$ depends on a subsequence.

**Proof.** Corollary 3.2 yields that $Q_k$, $k \in \mathbb{N}$ converges to a constant operator $Q$ such that $Q \chi = \{\tilde{w}\}$. Assume that $\lim_{l \to \infty} B_{1 \cdots B_l} = \tilde{C} \in \mathbb{P}M_n(C)$. Since $X$ has an interior, there exists an interior point $\tilde{x} \in \chi$ such that $x \not\in \ker C$. Hence $\tilde{w} = \lim_{l \to \infty} Q_{l}(\tilde{x}) = C\tilde{x} = Cx$. Since this result holds for any $y$ in the small neighborhood of $x$ it follows that $C$ is a rank one matrix of the form $wz^T$. 

4 Proof of Theorem 1.1 and Theorem 1.2 for $\mathbb{C}$

A special version of the following weak generalization of Theorem 3.4 will be needed to prove Theorem 1.2 in the complex case. Recall that $\mathbb{P}^n$ is a compact complex manifold. Let $d(\cdot, \cdot)$ be the Fubini-Study metric on $\mathbb{P}^n$ [6]. Then $\mathbb{P}^n$ has a finite diameter.

Let $\chi \subset \mathbb{P}^n$ be a compact set with respect to the Fubini-Study metric $d$ on $\chi$ and assume that $\chi$ has a nonempty interior. Let $B_k \in M_n(C)$, $k \in \mathbb{N}$ be a sequence of matrices such that $\overline{\ker B_k} \cap \chi = \emptyset$ and $T_k := B_k : \chi \to \chi$ for each $k \in \mathbb{N}$. Let $Q_k := T_1 \cdots T_k$, $k \in \mathbb{N}$. Assume that $\lim_{k \to \infty} L(Q_k) = 0$. Then $Q_k$ converges pointwise to a constant operator $Q : \chi \to \{\tilde{w}\}$ for some $\tilde{w} \in \chi$. Furthermore the limit of any convergent subsequence $\lim_{l \to \infty} B_{1 \cdots B_l} = \tilde{C} \in \mathbb{P}M_n(C)$ is of the form $\tilde{w} z^T$, where $z$ depends on a subsequence.

**Proof.** Corollary 3.2 yields that $Q_k$, $k \in \mathbb{N}$ converges to a constant operator $Q$ such that $Q \chi = \{\tilde{w}\}$. Assume that $\lim_{l \to \infty} B_{1 \cdots B_l} = \tilde{C} \in \mathbb{P}M_n(C)$. Since $\chi$ has an interior, there exists an interior point $\tilde{x} \in \chi$ such that $x \not\in \ker C$. Hence $\tilde{w} = \lim_{l \to \infty} Q_{l}(\tilde{x}) = C\tilde{x} = Cx$. Since this result holds for any $y$ in the small neighborhood of $x$ it follows that $C$ is a rank one matrix of the form $wz^T$. 

Corollary 5.2 gives a family of examples for which Theorem 3.6 applies.

**Theorem 3.6** Let $X \subset \mathbb{P}^n$ be a compact set with respect to the Fubini-Study metric $d$ on $\chi$ and assume that $\chi$ has a nonempty interior. Let $B_k \in M_n(C)$, $k \in \mathbb{N}$ be a sequence of matrices such that $\overline{\ker B_k} \cap \chi = \emptyset$ and $T_k := B_k : \chi \to \chi$ for each $k \in \mathbb{N}$. Let $Q_k := T_1 \cdots T_k$, $k \in \mathbb{N}$. Assume that $\lim_{k \to \infty} L(Q_k) = 0$. Then $Q_k$ converges pointwise to a constant operator $Q : \chi \to \{\tilde{w}\}$ for some $\tilde{w} \in \chi$. Furthermore the limit of any convergent subsequence $\lim_{l \to \infty} B_{1 \cdots B_l} = \tilde{C} \in \mathbb{P}M_n(C)$ is of the form $\tilde{w} z^T$, where $z$ depends on a subsequence.

**Proof.** Corollary 3.2 yields that $Q_k$, $k \in \mathbb{N}$ converges to a constant operator $Q$ such that $Q \chi = \{\tilde{w}\}$. Assume that $\lim_{l \to \infty} B_{1 \cdots B_l} = \tilde{C} \in \mathbb{P}M_n(C)$. Since $\chi$ has an interior, there exists an interior point $\tilde{x} \in \chi$ such that $x \not\in \ker C$. Hence $\tilde{w} = \lim_{l \to \infty} Q_{l}(\tilde{x}) = C\tilde{x} = Cx$. Since this result holds for any $y$ in the small neighborhood of $x$ it follows that $C$ is a rank one matrix of the form $wz^T$. 

Corollary 5.2 gives a family of examples for which Theorem 3.6 applies.
Let \( C_k := A_k A_{k-1} \ldots A_2 A_1, k \in \mathbb{N} \). Assume that \( \hat{C}_k \rightarrow \hat{C} \). Since \( \mathbb{P}^n \) is compact from each subsequence \( \hat{x}_{k_i} \) we can find as subsequence \( \hat{x}_{l_i} \) such that \( \hat{x}_{l_i} \rightarrow \hat{y} \) where \( y \in \mathbb{R}^n \) is a probability vector. Since \( \{ A_k \ldots A_1 \} \sim \{ x_k w^T \} \) it follows that \( \hat{C}_{l_i} \rightarrow \hat{y} w^T \).

We first deduce the theorem in the case \( A \) is a rank one matrix \( A = uv^T \). Assume that \( \hat{C}_{k_i} \rightarrow \hat{y} w^T \). From the sequence \( k_i \) pick up a subsequence \( p_q \) such that \( \hat{C}_{p_q-1} \rightarrow \hat{z} w^T \) for some probability vector \( z \). Under the above assumptions

\[
\lim_{p_q \to \infty} \hat{C}_{p_q} = \lim_{p_q \to \infty} A_{p_q} \hat{C}_{p_q-1} = uv^T zw^T = uv^T.
\]

Therefore \( \lim_{k \to \infty} \hat{C}_k = \hat{u} w^T \) and the theorem follows.

We now consider the general case. Without loss of generality we assume that the spectral radius of \( A \) is equal to 1. Then \( A^m \rightarrow uv^T \), where \( u^T v = 1 \). Choose \( \epsilon_m, m \in \mathbb{N} \) a sequence of positive decreasing numbers tending to zero with the following property:

\[
X_1, \ldots, X_m \in M_n(\mathbb{R}) \text{ and } ||X_i - A|| < \epsilon_m, i = 1, \ldots, m \Rightarrow ||X_1 X_2 \ldots X_m - A^m|| < \frac{1}{m}.
\]

Let \( N_m \) the following increasing sequence: \( ||A_k - A|| < \epsilon_m \) for each \( k > N_m \). Hence \( ||A_{j+m} \ldots A_{j+1} - A^m|| < \frac{1}{m} \) for any \( j > N_m \).

Let \( C_k := A_k A_{k-1} \ldots A_2 A_1, k \in \mathbb{N} \). Assume that \( \hat{C}_{k_i} \rightarrow \hat{y} w^T \). First choose a subsequence \( \{ q_j \} \) of \( \{ k_i \} \) such that \( q_{j+1} - q_j > N_{j+1} + j + 1 \), where \( q_0 = 0 \). Let \( r_j = q_j - j \) for \( j \in \mathbb{N} \). Note that \( r_{j+1} > q_j + N_{j+1} \). Hence

\[
||A_{q_j} \ldots A_{r_j+1} - A^j|| < \frac{1}{j}, \quad \text{for all } j \in \mathbb{N}.
\]

From the sequence \( r_j, j \in \mathbb{N} \) choose a subsequence \( r_{jm} \) such that \( \hat{C}_{r_{jm}} \rightarrow \hat{z} w^T \) for a probability vector \( z \in \mathbb{R}^n \). Note that since \( r_{jm} + jm = q_{jm} \) it follows that \( \hat{C}_{q_{jm}} \rightarrow \hat{y} w^T \). On the other hand \( \hat{C}_{q_{jm}} = A_{q_{jm}} \ldots A_{r_{jm}+1} \hat{C}_{r_{jm}} \). Our assumptions yield that the second factor converges to \( \hat{z} w^T \). Our construction yields that the first factor converges to \( u v^T \). Hence \( \hat{C}_{k_i} \rightarrow \hat{u} w^T \) and the theorem follows in this case too.

Let \( A \in M_n(\mathbb{R}) \) be a primitive matrix. Then \( A \) is row and column allowable. Furthermore \( \rho(A) > 1 \) and there exists \( u, v \in \mathbb{R}_+^n, v^T u = 1 \) such that \( A u = \rho(A) u, v^T A = \rho(A) v^T \). Moreover \( \lim_{m \to \infty} \rho(A)^{-m} A^m = uv^T \). The arguments of the proof of Theorem 1.1 yield:
Corollary 4.2 Let $A_k, k \in \mathbb{N}$ be a sequence of column allowable matrices such that $\lim_{k \to \infty} A_k = A$, where $A$ is a primitive matrix. Then (1.2) and (1.4) hold.

Proof of Theorem 1.2 in the real case. We assume that $A_k \in M_n(\mathbb{R}), k \in \mathbb{N}$. Hence $\lim_{k \to \infty} A_k = A \in M_n(\mathbb{R})$. Since the nonreal eigenvalues of $A$ come in pairs $\pm \rho$, it follows that the unique eigenvalue of $A$ on the circle $\{ z : |z| = \rho(A) \}$ is equal to $\pm \rho(A)$. By multiplying each $A_k$ and $A$ by $\pm \rho(A)^{-1}$ we may assume that $\rho(A) = 1$ and 1 is an eigenvalue of $A$. 1 is a simple eigenvalue of the characteristic polynomial of $A$ and all other eigenvalues of $A$ lie inside the unit disk $|z| < 1$. By considering $TA_kT^{-1}$ instead of $A_k$ and $TAT^{-1}$ instead of $A$ it is enough to prove the theorem in the case

$$Ae = e, \quad A^Tv = v, \quad e = (1, ..., 1)^T, \quad v = (v_1, ..., v_n)^T \in \mathbb{R}_+^n, \quad v_1 + ... + v_n = 1.$$ 

Indeed, since 1 is a simple root the characteristic polynomial of $A$, there exists $Q \in \text{GL}_n(\mathbb{R})$ such that $B := QAQ^{-1} = (1) \oplus B'$ for some $B' \in M_{n-1}(\mathbb{R})$. Hence $Be_1 = Be_1^T = e_1 = (1, 0, ..., 0)^T$. We claim that for $n \geq 2$ there exists $S \in \text{GL}_n(\mathbb{R})$ such that

$$Se_1 = e, \quad S^Tv = e_1, \quad \text{for any } v \in \mathbb{R}_+^n, \quad e^Tv = 1.$$ 

The first equation yields that the first column of $S$ is $e$. The second equation yields that the last $n-1$ columns of $S$ orthogonal to $v$. Pick any $n-1$ linearly independent vectors in $s_2, ..., s_n \in \mathbb{R}^n$ which are orthogonal to $v$. Then $S := (e_1, s_2, ..., s_n) \in \text{GL}_n(\mathbb{R})$ satisfies the above condition. Now let $T = SQ$.

Our assumptions yield

$$\lim_{m \to \infty} A^m = evT.$$ 

As in the proof of Theorem 1.1, let us consider first the case $A = ev^T$. As $\lim_{k \to \infty} A_k = A$ and $A$ is a positive matrix it follows that $A_k \in M_n(\mathbb{R}_+)$ for $k \geq M$. Theorem 1.1 yields that $A_k...A_M$ converges to $e\hat{w}_0$. Hence $\lim_{k \to \infty} A_k...A_1 = e\hat{w}^T$, where $w^T = w_0^TA_{M-1}...A_1$. This proves the theorem in this case.

Assume that $A \neq ev^T$. As $\lim_{m \to \infty} A^m = ev^T$ it follows that there exists $m \in \mathbb{N}$ such that $A^m \in M_n(\mathbb{R}_+)$. Hence $A_{k+m-1}...A_k \in M_n(\mathbb{R}_+)$ for $k \geq N$. Theorem 1.1 yields that $\lim_{k \to \infty} A_{km+N}...A_{N+1} \to e\hat{w}_0^T$. Hence

$$\lim_{k \to \infty} A_{km+N}...A_{N+1} = A^j\hat{w}_0^T = e\hat{w}_0^T$$

and the theorem follows in this case too.
5 Proof of Theorem 1.2 in the complex case.

Since $M_n(C) \sim C^{n^2}$ it follows that $PM_n(C) \sim \mathbb{P}C^{n^2}$. Let $d_1$ be the Fubini-Study metric on $PM_n(C)$. Let $A \in PM_n(C)$. Then $A : \mathbb{P}C^n \backslash \text{ker} A \to \mathbb{P}C^n$ is a holomorphic map.

**Lemma 5.1** Let $E \in M_n(C)$ be rank one matrix with $\rho(E) > 0$, i.e. $E = vu^T, u^Tv \neq 0$. Let $O_r := \{x \in \mathbb{P}C^n : d(x, \hat{v}) \leq r\}$ such that $O_r \cap \text{ker} \ E = \emptyset$. Then $\hat{E} : O_r \to \{\hat{v}\}$. Assume that $E_k \in M_n(C) \setminus \{0\}$, $k \in \mathbb{N}$ converges to $E$. Then there exists $N$ such that $E_k : O_r \to \{\hat{v}\}$ is a sequence of uniform contractions for $k > N$, i.e. $d(\hat{E}_k \hat{x}, \hat{E}_k \hat{y}) \leq \kappa d(\hat{x}, \hat{y})$ for all $\hat{x}, \hat{y} \in O_r$ some $\kappa \in (0, 1)$ and $k > N$. Moreover there exists $\epsilon > 0$, depending on $E$, $r$ and $\kappa \in (0, 1)$, such that for each $\hat{B} \in \mathbb{P}M_n(C)$ satisfying $d_1(\hat{B}, \hat{E}) \leq \epsilon$ one has $\hat{B} : O_r \to O_r$ and $L(\hat{B}) \leq \kappa$.

**Proof.** Clearly $\hat{E}x = \hat{v}$ if $u^Tx \neq 0$. Hence $\hat{E} : O_r \to \{\hat{v}\}$. Since $\text{ker} E_k$ converges $\text{ker} \ E$ it follows that $\hat{E}_k|O_r$ converges uniformly to $\hat{E}|O_r$. In particular $\hat{E}_k : O_r \to O_r$ for $k > M$.

Let $\hat{B} \in M_n(C) \setminus \{0\}$. Then for each $x \in \mathbb{P}C^n \backslash \text{ker} \hat{B}$ we can define the local distortion of $\hat{B}$ at $\hat{x}$:

$$\delta(\hat{B}, \hat{x}) = \lim_{m \to \infty} \sup_{\hat{y} \neq \hat{x}, d(\hat{y}, \hat{x}) \leq \frac{1}{m}, d(\hat{x}, \hat{z}) \leq \frac{1}{m}} \frac{d(\hat{B}\hat{y}, \hat{B}\hat{z})}{d(\hat{y}, \hat{z})}.$$

For any $\mathcal{Y} \subset \mathbb{P}C^n \backslash \text{ker} \hat{B}$ let

$$\delta(\hat{B}, \mathcal{Y}) := \sup_{\hat{x} \in \mathcal{Y}} \delta(\hat{B}, \hat{x}).$$

Recall that a set $\mathcal{Y}$ is called convex if any two points $x, y \in \mathcal{Y}$ can be connected by a geodesic that completely lies in $\mathcal{Y}$. It is a standard fact that if $\mathcal{Y} \subset \mathbb{P}C^n \backslash \text{ker} \hat{B}$ is a convex set then

$$d(\hat{B}\hat{x}, \hat{B}\hat{y}) \leq \delta(\hat{B}, \mathcal{Y})d(\hat{x}, \hat{y}) \quad \text{for all } \hat{x}, \hat{y} \in \mathcal{Y}.$$ 

Clearly $\delta(\hat{E}, \hat{x}) = 0$ for all $\hat{x} \in \mathbb{P}C^n \backslash \text{ker} \hat{E}$. As $E_k \to E$ it follows that $\lim_{k \to \infty} \delta(\hat{E}_k, \hat{x}) = 0$ for all $\hat{x} \in \mathbb{P}C^n \backslash \text{ker} \hat{E}$. Use this fact and the fact that $O_r$ can be covered by a finite number of convex balls $\{\hat{y} : d(\hat{y}, \hat{x}) < r(\hat{x})\}, \hat{x} \in O_r$ to deduce the first part of the lemma.
We now deduce the second part of the lemma. Since $O_r$ and $\ker \hat{E}$ closed and disjoint it follows that $d(O_r, \ker \hat{E}) = 2a > 0$. Hence there exists $\epsilon_1$ such that $d(O_r, \ker \hat{B}) \geq a$ if $d_1(B, \hat{E}) \leq \epsilon_1$. It is not difficult to show that

$$\lim_{t \to 0} \max_{d_1(B, \hat{E}) \leq t} \delta(B, O_r) = \delta(\hat{E}, O_r) = 0.$$ 

Hence for $\epsilon$ small enough and $d_1(\hat{B}, \hat{E}) \leq \epsilon$ one has $d(\hat{BO}_r, \hat{EO}_r) = d(\hat{BO}_r, \hat{u}) < r$ and $L(\hat{B}) = \delta(B, O_r) < \kappa$. \hfill \Box

**Corollary 5.2** Let $E \in M_n(\mathbb{C})$ be a rank one nonnilpotent matrix and let $r > 0$, $\kappa \in (0,1)$ be given as in Lemma 5.1. Let $B_k \in M_n(\mathbb{C}) \setminus \{0\}$ and assume that $d_1(\hat{B}_k, \hat{E}) \leq \epsilon$ for each $k \in \mathbb{N}$. Then for $\mathcal{X} = O_r$ the assumptions of Theorem 3.6 hold.

In what follows we use the concepts of the exterior products $\wedge_k \mathbb{F}^n \subset \mathbb{F}^n(k)$ and the operators $\wedge_k A \in M_n(\mathbb{F})$ induced by $A \in M_n(\mathbb{F})$. In matrix theory $\wedge_k A$ is called $k$-th compound matrix, and its entries are given as the $k \times k$ minors of $A$. For any $x_1, ..., x_k \in \mathbb{F}^n$ the coordinates of $x_1 \wedge ... \wedge x_k \in \wedge^k \mathbb{F}^n$ are $\binom{n}{k}$ minors of the $n \times k$ matrix $(x_1 \ldots x_k)$ arranged in the lexicographical order. Note any nonzero vector $x_1 \wedge ... \wedge x_k$ represents a unique subspace $X = \text{span}(x_1, ..., x_k)$ of dimension $k$, which is an element of the Grassmannian $\text{Gr}(k, n, \mathbb{F})$. Then $y_1 \wedge ... \wedge y_k$ represents $X$ if and only if $\text{span}(y_1, ..., y_k) = \text{span}(x_1, ..., x_k)$. See for example [5] for the properties of the compound matrices and [3] for a concise survey of multilinear algebra used in this paper.

In particular we use the following facts. Let $A, B \in M_n(\mathbb{C})$. Then

(a) $\wedge_k AB = \wedge_k A \wedge_k B$.

(b) $Ax_1 \wedge ... \wedge Ax_k = \wedge_k A(x_1 \wedge ... \wedge x_k)$. If $x_1, ..., x_k$ spans a $k$-dimensional invariant subspace of $A$ then $x_1 \wedge ... \wedge x_k$ is an eigenvector of $\wedge_k A$. In particular if $x_1, ..., x_k$ are $k$-linearly independent eigenvectors of $A$ corresponding to the eigenvalues $\lambda_1, ..., \lambda_k$ then $x_1 \wedge ... \wedge x_k$ is an eigenvector of $\wedge_k A$ corresponding to the eigenvalue $\lambda_1 \cdots \lambda_k$.

(c) Let $\lambda_1, ..., \lambda_n$ be the eigenvalues of $A$ counting with their multiplicities. Then $\lambda_{i_1} \cdots \lambda_{i_k}$ for all $1 \leq i_1 < ... < i_k \leq n$ are all $\binom{n}{k}$ eigenvalues of $\wedge_k A$.

**Proof of Theorem 1.2 in the complex case.**

By our assumptions the spectral circle $\{z : |z| = \rho(A)\}$ contains exactly one eigenvalue $\lambda$ of algebraic multiplicity 1. By considering $\rho(A)^{-1} A$ we may assume that 1 is a simple algebraic eigenvalue of $A$, while other eigenvalues of $A$ are in the open unit disk. Hence $\lim_{k \to \infty} A^m = uv^T$, $u^Tv = 1$. Let $E := vu^T$. Lemma 5.1
yields that there exists $\epsilon > 0$ so that for each $B \in M_n(\mathbb{C})$ satisfying $d_1(\hat{B}, \hat{E}) \leq \epsilon$ one has $\hat{B} : O_r \to O_r$ and $L(\hat{B}, O_r) \leq \frac{1}{2}$. From the arguments of the proof of Theorem 1.1 it follows that there exists $m \in \mathbb{N}, N \in \mathbb{Z}_+$ such that $d_1(A_{k+1}^T \ldots A_{k+m}^T, \hat{E}) \leq \epsilon$ for any $k \geq N$.

Note that for $k > N$ we have $C_k = A_k \ldots A_1 = C_{N+1,k}Q_N$, where $C_{p,k} := A_k A_{k-1} \ldots A_{p+1} A_p, p \leq k \in \mathbb{N}$ and $Q_0 = I$ if $N = 0$ and $Q_N := A_N \ldots A_1$ if $N \geq 1$. Since $A_j \in \text{GL}_n(\mathbb{C})$ for $j \in \mathbb{N}$ to prove the theorem it is enough to consider the case $N = 0$. That is we assume that the sequence $A_k^T \ldots A_{k+m-1}^T : O_r \to O_r, k \in \mathbb{N}$ is a sequence of uniform contractions on $O_r$. Corollary 3.2 implies that $\lim_{k \to \infty} C_{j,mk+j-1}^T \hat{x} = \hat{w}_j$ for any $\hat{x} \in O_r$ and some $\hat{w}_j \in O_r$ for $j = 1, \ldots, m$.

Assume that $\hat{C}_{k_l} \to \hat{C} \in \mathbb{P} M_n(\mathbb{C})$, where $C \in M_n(\mathbb{C}) \setminus \{0\}$. We claim that

$$
\lim_{l \to \infty} A_{k_l} \ldots A_1 = \hat{C} = zy^T, \text{ for some } y, z \in \mathbb{C}^n \setminus \{0\}. \tag{5.1}
$$

Choose a subsequence $\{p_q\}_{q \in \mathbb{N}}$ of $\{k_l\}_{l \in \mathbb{N}}$ such that each $p_q - (j - 1)$ is divisible by $m$ for some $j \in [1, m] \cap \mathbb{N}$. Then Theorem 3.6 yields that $\lim_{q \to \infty} C_{j,p_q}^T \hat{w} = \hat{w}_j z^T$. Hence $C = zy^T$ where $y = A_1^T \ldots A_{j-1}^T \hat{w}_j, \text{ where } A_0 = I$.

To prove the theorem it is enough to show that $z \in \text{span}(u)$ and $y \in \text{span}(w)$ for some fixed $w \in \mathbb{C}^n \setminus \{0\}$. This is done by converting the complex matrices to the real matrices of double dimension, taking the second compounds of the corresponding matrices and using the results of Theorem 1.2 for the real case.

Recall that any linear transformation of $\mathbb{C}^n$ to itself represented by a matrix $L \in M_n(\mathbb{C}), L = P + \sqrt{-1}Q, P, Q \in M_n(\mathbb{R})$ can be presented by $\tilde{L} := \begin{pmatrix} P & -Q \\ Q & P \end{pmatrix}$. This is done by representing any $z \in \mathbb{C}^n, z = x + \sqrt{-1}y, x, y \in \mathbb{R}^n$ by $\tilde{z} := (x^T, y^T)^T \in \mathbb{R}^{2n}$. Then $Lz = \tilde{L}z$ and $L_1L_2 = \tilde{L}_1\tilde{L}_2$ for any $L_1, L_2 \in M_n(\mathbb{C})$. Note that one dimensional subspace $\text{span}(z) \in \mathbb{C}^n, z \neq 0$ corresponds to the two dimensional subspace $\text{span}(z, \sqrt{-1}z) \in \mathbb{R}^{2n}$. Assume that $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of $L$ counted with their multiplicities. It is straightforward to show $\lambda_1, \overline{\lambda_1}, \ldots, \lambda_n, \overline{\lambda_n}$ are the eigenvalues of $\tilde{L}$ counted with their multiplicities. (For a diagonal $L$ the proof reduces to the case where $L \in M_1(\mathbb{C})$.) Moreover if $L$ is rank one nonnilpotent then $\tilde{L}$ is rank two diagonalizable.

The assumptions of the theorem yield that $\tilde{A}_k \in \text{GL}_{2n}(\mathbb{R}), k \in \mathbb{N}$ and $\lim_{k \to \infty} \tilde{A}_k = \tilde{A}$. Hence $\wedge_2 \tilde{A}_j \in \text{GL}_{(2^n)}(\mathbb{R})$ and $\lim_{k \to \infty} \wedge_2 \tilde{A}_k = \wedge_2 \tilde{A}$. Since $A$ was rank one non-nilpotent matrix $\tilde{A}$ is a rank two diagonalizable matrix. Hence $\wedge_2 \tilde{A}$ is a rank one matrix with the eigenvector $\tilde{u} \wedge \sqrt{-1}u$ corresponding to the eigenvalue $|\lambda|^2 > 0$. Thus we
can apply real version Theorem 1.2 for the sequence \( \wedge_2 A_k, k \in \mathbb{N} \). Hence

\[
\lim_{k \to \infty} \wedge_2 \tilde{A}_k \cdots \wedge_2 \tilde{A}_1 = \hat{F}, \quad F = (\tilde{u} \wedge \sqrt{-1} \tilde{u}) s^T, \quad \text{for some } s \in \mathbb{R}_{(2)}^{(n)} \setminus \{0\}.
\]

Compare that with (5.1) to deduce that \( \wedge_2 z^{T} y = \hat{F} \). Equivalently \( \wedge_2 z^{T} y = aF \) for some \( a \neq 0 \). This shows that first that \( z \in \text{span}(u) \). Second that \( \tilde{y} \wedge \sqrt{-1} \tilde{y} = s \).

Since \( s \) is fixed the one dimensional subspace \( \text{span}(y) \) does not depend on the convergent subsequence \( C_{\tilde{k}_l}, l \in \mathbb{N} \). Thus we can choose \( w \) to be equal to \( y \) for one convergent subsequence \( C_{\tilde{k}_l}, l \in \mathbb{N} \).

\[ \square \]

6 Finer results

The aim of this section is to consider the convergence of \( A_k \cdots A_1 x_0 \) under the assumptions of Theorems 1.1 and 1.2 when \( w^T x_0 = 0 \). In this case we need to pass to the exterior products. In this section we assume that the vector and operator norms on \( \mathbb{F}^n \) and \( M_n(F) \) for \( F = \mathbb{R}, \mathbb{C} \) are the \( l_2 \) norms \( || \cdot ||_2 \).

To extend the results of Theorem 1.1 one needs to recall the notions of strictly totally positive matrices and (discrete) Tchebyshev systems. See for example [5] or [10] for the notion of strictly totally positive matrices and [10] for the classical notion of Tchebyshev systems. We call \( x_1, \ldots, x_p \in \mathbb{R}^n \) a \( p \)-Tchebyshev system if \( x_1 \in \mathbb{R}_+, x_1 \wedge x_2 \in \mathbb{R}_+^{(1)}, \ldots, x_1 \wedge \cdots \wedge x_p \in \mathbb{R}_+^{(p)} \). A vector \( x \in \mathbb{R}^n \) is said to have exactly \( k \)-changes of signs, denoted by \( S(x) = k \), if by replacing any zero coordinate of \( x \) by a positive or negative number one obtains a vector \( y \) whose coordinates have exactly \( k \) changes of signs.

It is straightforward to show that if \( S(x) = k \leq n - 1 \), there exists a \( k \)-Tchebyshev system \( x_1, \ldots, x_k \) such that \( x_k = \pm x \).

Recall that \( A \in M_n(\mathbb{R}) \) is called strictly totally positive of order \( p \in [1, n] \cap \mathbb{Z} \) (\( STP_p \)) if \( \wedge_k A \in M_n^{(k)}(\mathbb{R}_+) \) for \( k = 1, \ldots, p \). (Here \( \wedge_1 A := A \).) That is \( A \) and all its \( k \leq p \) compounds are positive. The spectrum of \( A \) spec \( A \) is of the form \( \{\lambda_1, \ldots, \lambda_p\} \cup \text{spec}_{p+1} A \). Here \( \lambda_1 > \cdots > \lambda_p > 0 \) are \( p \) positive real numbers and \( \text{spec}_{p+1} A \subset \{z \in \mathbb{C} : |z| < \lambda_p \} \) if \( p < n \). (spec \( n+1 A = \emptyset \).) Each \( \lambda_i \) is a simple root of \( \det(zI - A) \) for \( i = 1, \ldots, p \). Furthermore one can choose the signs of the eigenvectors of \( A \) and \( A^T \) corresponding to \( \lambda_1, \ldots, \lambda_k \) such that they form Tchebyshev systems:

\[
Au_i = \lambda_i u_i, ||u_i|| = 1, S(u_i) = i - 1, i = 1, \ldots, p, u_1 \in \mathbb{R}_+^n, \ldots, u_1 \wedge \cdots \wedge u_p \in \mathbb{R}_+^{(p)},
\]

14
\[ A^T v_i = \lambda_i v_i, \quad S(v_i) = i - 1, \quad i = 1, \ldots, p, \quad v_1 \in \mathbb{R}^n_+, \ldots, v_1 \wedge \ldots \wedge v_p \in \mathbb{R}^n_+^{(p)}, \]
\[ v_1^T u_j = \delta_{ij}, \quad i, j = 1, \ldots, p. \]  

(6.1)

**Theorem 6.1** Let \( A_k \in M_n(\mathbb{R}^+_0), k \in \mathbb{N} \) be a sequence of STP \( p \) matrices which converge to a STP \( p \) matrix \( A \in M_n(\mathbb{R}^+_0) \) for some \( p \in [2, n] \) satisfying (6.1). Then there exists a \( p \)-Tchebyshev system \( w_1, \ldots, w_p \) such that the following conditions hold. Let \( C_k = A_{k-1} \ldots A_1 \) for \( k \in \mathbb{N} \). Then

\[
\lim_{k \to \infty} \frac{\lambda_{i+1}(C_k)}{\lambda_i(C_k)} = 0, \quad i = 1, \ldots, p - 1, \tag{6.2}
\]

\[
\lim_{k \to \infty} \frac{\lambda_i(C_k)}{\rho_i(C_k)} = \frac{\lambda_i(C_k)}{\rho_i(C_k)} \quad \text{for all } i, k.
\tag{6.3}
\]

\[
C_k = \sum_{i=1}^{p} \lambda_i(C_k) u_{i,k} w^T_{i,k} + o(\|\lambda_p(C_k)\|), \quad \|w^T_{i,k} u_{j,k}\| = \delta_{ij}, \tag{6.4}
\]

\[
C_k u_{i,k} = \lambda_i(C_k) u_{i,k}, \quad \|u_{i,k}\| = 1, \quad C_k w^T_{i,k} = \lambda_i(C_k) w_{i,k}, \tag{6.5}
\]

\[
u_{1,k} \wedge \ldots \wedge u_{i,k}, \quad w_{1,k} \wedge \ldots \wedge w_{i,k} \in \mathbb{R}^n_+^{(i)}, \tag{6.6}
\]

**Proof.** Assume first the assumptions of Theorem 1.1. Let \( u_{1,k}, w_{1,k} \) be as above. Assume furthermore that \( \|u_{1,k}\| = 1 \). From the proof of Theorem 1.1 it follows that \( u_{1,k} \to u_1 = u \). Let \( E \) be defined by (1.2). Then \( \rho(E) = w^T u \). Hence

\[
\frac{\lambda_1(C_k)}{\|u_1\|} \to \frac{w^T u}{\|u\| \|w\|}. \tag{6.7}
\]

Hence (6.3) holds for \( p = 1 \). The proof of Theorem 1.1 yields that one has the equality (6.4) for \( p = 1 \). Here \( w_1 = (w^T u)^{-1} w \).

We now show the theorem for the case \( p = 2 \). Let \( M_2(\mathbb{R}^+_0) \ni B_k := \wedge_2 A_k \to B := \wedge_2 A \in M_2(\mathbb{R}^+_0) \). As \( \frac{\lambda_1(C_k)}{\|C_k\|} \to \|\lambda_1 w_1\|^{-1} \) (1.2) yields (6.2) for \( p = 2 \). Let \( D_k := B_k \ldots B_1, k \in \mathbb{N} \). Clearly \( \lambda_1(D_k) = \lambda_1(C_k) \lambda_2(C_k) \) and the corresponding Perron eigenvectors of \( D_k \) are \( u_{1,k} \wedge u_{2,k}, w_{1,k} \wedge w_{2,k} \in \mathbb{R}^n_+^{(2)} \). Then Theorem 1.1 applied to \( B_k, k \in \mathbb{N} \) yields that

\[
\text{span}(u_{1,k}, u_{2,k}) \to U_2 = \text{span}(u_1, u_2) \in \text{Gr}(2, n, \mathbb{R}), \quad \text{span}(w_{1,k}, w_{2,k}) \to W_2 \in \text{Gr}(2, n, \mathbb{R}).
\]

As \( w^T_{1,k} u_{2,k} = 0 \), \( \|u_{2,k}\| = 1 \) and \( w_{1,k} \to w_1 \) it follows that \( \text{span}(u_{2,k}) \to \text{span}(u_2) \).

As \( u_{1,k} \wedge u_{2,k} \in \mathbb{R}^n_+^{(2)} \), it follows that \( u_{2,k} \to u_2 \). Clearly \( w_1 \in W_2 \). As \( w^T_{2,k} u_{1,k} = 0 \), \( w^T_{2,k} u_{2,k} = 1 \) it follows that \( w_{2,k} \to w_2 \), which is the unique vector in \( W_2 \).
satisfying the conditions \( w^T \mathbf{u}_1 = 0, \ w^T \mathbf{u}_2 = 1 \). So \( w_{1,k} \wedge w_{2,k} \rightarrow w_1 \wedge w_2 \in \mathbb{R}^+, \) which is the positive eigenvector of the following rank one matrix

\[
E_2 := \frac{\mathbf{u}_1 \wedge \mathbf{u}_2 (w_1 \wedge w_2)^T}{\|\mathbf{u}_1 \wedge \mathbf{u}_2\| \|w_1 \wedge w_2\|} = \lim_{k \to \infty} \frac{D_k^T}{\|D_k^T\|}.
\]

The above equality is equivalent to (6.3) for \( i = 2 \).

Recall that all the eigenvalues of \( D_k \) are of the form \( \lambda \mu, \lambda, \mu \in \text{spec} (C_k) \), where either \( \lambda \neq \mu \) or \( \lambda = \mu \) is a multiple eigenvalue of \( D_k \). Thus if \( |\lambda| \geq |\mu| \) then \( \lambda_2(D_k) > |\mu| \) unless \( \lambda = \lambda_1(D_k), \mu = \lambda_2(C_k) \). Combine all these facts to obtain (6.4) for \( p = 2 \).

Assume now that \( p > 2 \). By considering the compound matrices \( \wedge_i A_k, k \in \mathbb{N} \) for \( i = 3, ..., p \) we deduce the rest of theorem as in the case \( p = 2 \).

Assume the assumptions of Theorem 6.1. Let \( \mathbf{z} \in \mathbb{R}^n \) and \( S(\mathbf{z}) = p - 1 \). Since \( \pm \mathbf{z} \) can be completed to a \( p \) Tchebyshev \( \mathbf{z}_1, ..., \mathbf{z}_p \) it follows that it is impossible that \( w_i^T \mathbf{z} = 0 \) for \( i = 1, ..., p \). Thus one can estimate the behavior of \( \widehat{C}_k \mathbf{z} \) as \( k \to \infty \).

**Theorem 6.2** Let \( A_k \in \text{GL}_n(\mathbb{C}), k \in \mathbb{N} \). Assume that for \( k > N \) the following conditions satisfied: For \( p \in [1,n] \cap \mathbb{Z} \) there exists \( \alpha \in (0,1) \) and:

(a) biorthonormal sets \( \mathbf{x}_{i,k}, ..., \mathbf{x}_{p,k}; \mathbf{y}_{1,k}, ..., \mathbf{y}_{p,k} \in \mathbb{C}^n \) such that

\[
\|\mathbf{x}_{i,k}\| = 1, \ \mathbf{y}_{i,k}^T \mathbf{x}_{j,k} = \delta_{ij}, \ i, j = 1, ..., p, \ k > N,
\]

\[
\lim_{k \to \infty} \mathbf{x}_{i,k} = \mathbf{u}_i, \ \|\mathbf{u}_i\| = 1, \ \lim_{k \to \infty} \mathbf{y}_{i,k} = \mathbf{v}_i, \ \mathbf{v}_i^T \mathbf{u}_j = \delta_{ij}, \ i, j = 1, ..., p.
\]

(b) \( \lambda_{1,k}, ..., \lambda_{p,k} \in \text{spec} (A_k) \) are simple roots of the characteristic polynomial of \( A_k \) such that

\[
A_k \mathbf{x}_{i,k} = \lambda_{i,k} \mathbf{x}_{i,k}, \ A_k^T \mathbf{y}_{i,k} = \lambda_{i,k} \mathbf{y}_{i,k}, \ |\lambda_{i,k}| \geq \alpha |\lambda_{i+1,k}|, \ i = 1, ..., p, \ \text{for any} \ k > N,
\]

where \( \lambda_{p+1,k} \) is any eigenvalue of \( A_k \) different from \( \lambda_{1,k}, ..., \lambda_{p,k} \). Furthermore, there exists an operator norm \( \|\cdot\| : M_n(\mathbb{C}) \to [0, \infty) \) such that

\[
\|\|A_k - \sum_{i=1}^{p} \lambda_{i,k} \mathbf{x}_{i,k} \mathbf{y}_{i,k}^T\|\| \leq \alpha |\lambda_{p,k}|, \ k > N. \tag{6.7}
\]

Let \( C_k := A_k ... A_1, k \in \mathbb{N} \). Then there exists \( N_1 > N \) that for \( k > N_1 \) the following conditions hold. \( C_k \) has \( p \) simple eigenvalues \( \lambda_1(C_k), ..., \lambda_p(C_k) \) such that \( |\lambda_1(C_k)| > ... > |\lambda_p(C_k)| \). It is possible to choose the corresponding eigenvectors of \( C_k, C_k^T \) as \( \mathbf{u}_{1,k}, ..., \mathbf{u}_{p,k}, \mathbf{w}_{1,k}, ..., \mathbf{w}_{p,k} \) such that equalities (6.2) - (6.6) hold.
Proof. We first consider the case $p = 1$. By considering the matrices $\lambda_{1,k}^{-1} A_k$ it is enough to prove the above theorem in the case $\lambda_{1,k} = 1$ for $k > N$. Let $R_k := A_k - x_{1,k} y_{1,k}^T$ for $k > N$. The spectral decomposition of $A$ yields and (6.7) yields

$$R_k x_{1,k} = R_k^T y_{1,k} = 0, \quad |||R_k||| \leq \alpha, \quad k > N. \quad (6.8)$$

In order to use the arguments of the proof of Theorem 1.1 it is enough to show that for each $m > 1$ there exists $K(m)$ such that if $j > K(m)$

$$|||A_j + m \ldots A_{j+1} - u_1 v_1^T||| < |\alpha|^m + \frac{1}{m}. \quad (6.9)$$

Consider the product

$$A_j + m \ldots A_{j+1} = (x_{1,j+m} y_{1,j+m}^T + R_{j+m}) \ldots (x_{1,j+1} y_{1,j+1}^T + R_{j+1}). \quad (6.10)$$

Expand this product to $2^m$ terms. The first term in this product is

$$x_{1,j+m} y_{1,j+m}^T \ldots x_{1,j+1} y_{1,j+1}^T = \left( \prod_{i=j+1}^{j+m-1} y_{1,i+1}^T x_{1,i} \right) x_{1,j+m} y_{1,j+1}^T.$$

Hence it converges to $u_1 v_1^T$ as $j \to \infty$. Consider the last term in (6.10). Since $||| \cdot |||$ is an operator norm

$$|||R_{j+m} \ldots R_{j+1}||| \leq |||R_{j+m}||| \ldots |||R_{j+1}||| \leq \alpha^m.$$

It is left to show that that all other $2^m - 2$ terms in (6.10) tend to zero. Each of this term contains either a factor $x_{j+i+1} y_{j+i+1}^T R_{j+i}$ or $R_{j+i+1} x_{j+i} y_{j+i}^T$. Use (6.8) to deduce

$$x_{j+i+1} y_{j+i+1}^T R_{j+i} = x_{j+i+1} (y_{j+i+1} - y_{j+i})^T R_{j+i},$$

$$R_{j+i+1} x_{j+i} y_{j+i}^T = R_{j+i+1} (x_{j+i} - x_{j+i+1}) y_{j+i}^T.$$

If a term contains more then one of such factors choose the above modification at one factor exactly. Now estimate the norm of this term by taking the products of the norms of $m$ factors. It now follows that each of this terms tends to zero. Hence (6.9) follows. Now we can repeat the arguments of the proof of Theorem 1.2 to prove the theorem for $p = 1$.

To prove the theorem for $p > 1$ we consider the wedge products $\wedge_i A_k, k \in \mathbb{N}$ for $i \in [2, p]$. The spectral analysis of $\wedge_i A_k$ implies that $\wedge_i A_k, k \in \mathbb{N}$ satisfy the above conditions for $p = 1$. Use the arguments of the proof of Theorem 6.1 to deduce the

17
Assume that $R \in M_n(\mathbb{C})$ has a spectral radius $\rho(R) \in [0,1)$. It is well known that for any $\alpha \in (\rho(R),1)$ there exists an operator norm $\| \cdot \| : M_n(\mathbb{C}) \to [0,\infty)$ such that $\|R\| \leq \alpha$.

**Corollary 6.3** Let $A_k \in \text{GL}_n(\mathbb{C}), k \in \mathbb{N}$. Assume that $\lim_{k \to \infty} A_k = A \in M_n(\mathbb{C})$. Suppose furthermore that $\lambda_1, \ldots, \lambda_p$ are $p$ simple roots of $\det (zI - A)$, where $\rho(A) = |\lambda_1| > \ldots > |\lambda_p| > 0$. Assume furthermore that any other eigenvalue $\lambda \in \text{spec } A \setminus \{\lambda_1, \ldots, \lambda_p\}$ satisfies $|\lambda| < |\lambda_p|$. Then $A_k, k \in \mathbb{N}$ satisfy the assumptions of Theorem 6.2, where $Au_i = \lambda_i u_i, \ i = 1, \ldots, p$.
