Outline

1. Introduction.

2. Stochastic-Volatility Jump-Diffusion Model.

3. European Option Prices.

5. Numerical Results for Call and Put Options.

6. Conclusions.
1. Introduction

- **Classical Black-Scholes (1973) model fails** to reflect the three empirical phenomena:
  - Non-normal features: return distribution **skewed negative** and **leptokurtic**, with higher peak and heavier tails;
  - **Volatility smile**: implied volatility not constant as in B-S model;
  - Large, sudden movements in prices: **crashes and rallies**.
- Recently empirical research (Andersen et al.(2002), Bates (1996) and Bakshi et al.(1997)) imply that **most reasonable model of stock prices includes both stochastic volatility and jump diffusions**. Stochastic volatility is needed to calibrate the longer maturities and jumps are needed to reflect shorter maturity option pricing.
- **Log-uniform jump amplitude distribution is more realistic** and accurate to describe high-frequency data; square-root stochastic volatility process allows for systematic volatility risk and generates an analytically tractable method of pricing options.
2. Stochastic-Volatility Jump-Diffusion Model

- Assume asset price \( S(t) \), under a risk-neutral probability measure \( \mathcal{M} \), follows a jump-diffusion process and conditional variance \( V(t) \) follows a square-root mean-reverting diffusion process:

\[
\begin{align*}
    dS(t) &= S(t) \left( (r - \lambda \bar{J}) dt + \sqrt{V(t)} dW_s(t) \right) \quad dN(t) \\
    &= S(t) \left( (r - \lambda \bar{J}) dt + \sqrt{V(t)} dW_s(t) \right) + \sum_{k=1}^{dN(t)} S(T_k^-) J(Q_k),
\end{align*}
\]

\[
dV(t) = k (\theta - V(t)) dt + \sigma \sqrt{V(t)} dW_v(t). \tag{2}
\]

- \( r = \text{constant risk-free interest rate} \);
- \( W_s(t) \) and \( W_v(t) \) are standard Brownian motions with correlation: \( \text{Corr}[dW_s(t), dW_v(t)] = \rho \);
- \( J(Q) = \text{Poisson jump-amplitude}, Q = \text{underlying Poisson amplitude mark process} \) selected so that \( Q = \ln(J(Q) + 1) \);
- \( N(t) = \text{compound Poisson process} \) with jump intensity \( \lambda \).
• Density of jump-amplitude *mark Q is uniformly distributed*:

\[ \phi_Q(q) = \frac{1}{b-a} \begin{cases} 1, & a \leq q \leq b \\ 0, & \text{else} \end{cases} \quad , \quad a < 0 < b \]

- Mark Mean: \( \mu_j \equiv \mathbb{E}[Q] = 0.5(b + a) \);
- Mark Variance: \( \sigma_j^2 \equiv \text{Var}_Q[Q] = (b - a)^2 / 12 \);
- Jump-Amplitude Mean:

\[ \bar{J} \equiv \mathbb{E}[J(Q)] \equiv \mathbb{E}[\exp(Q) - 1] = (\exp(b) - \exp(a)) / (b-a) - 1. \]

- Realism: Jump amplitudes are finite; NYSE uses *circuit breakers* that limit very large jumps; in optimal portfolio problem finite distributions allow realistic borrowing and short-selling.

• By Itô’s chain rule, *log-return process* \( \ln(S(t)) \) satisfies SDE:

\[
d\ln(S(t)) = (r - \lambda \bar{J} - V(t)/2)dt + \sqrt{V(t)}dW_s(t) + \sum_{k=1}^{dN(t)} Q_k .
\]

(3)
3. European Option Prices

3.1 Probability Distribution Function:

• **Price of European call option** under risk-neutral probability measure:

\[
C(S(t), V(t), t; K, T) = e^{-r(T-t)}E_{\mathcal{M}}[\max[S_T - K, 0]|S(t), V(t)]
\]

(4)

\[
= S(t)P_1(S(t), V(t), t; K, T)
\]

\[-K e^{-r(T-t)}P_2(S(t), V(t), t; K, T);\]

• \(C(S(t), V(t), t; K, T)e^{r(T-t)} = E_{\mathcal{M}}[\max(S_T - K, 0)|S(t), V(t)],\) the conditional expectation of the composite process;

• **Change of variables:** \(L(t) = \ln(S(t))\) and \(\kappa = \ln(K),\) so

\(\hat{C}(L(t), V(t), t; \kappa, T) \equiv C(S(t), V(t), t; K, T)\) in terms of processes or for PDEs \(\hat{C}(\ell, v, t; \kappa, T) \equiv C(\exp(\ell), v, t; \exp(\kappa), T);\)

• Applying the two-dimensional Dynkin’s theorem,
using \( A \) as backward operator:

\[
0 = \frac{\partial \hat{C}}{\partial t} + A[\hat{C}](\ell, v, t; \kappa, T) \equiv \frac{\partial \hat{C}}{\partial t} + \left( r - \lambda \bar{J} - \frac{1}{2} v \right) \frac{\partial \hat{C}}{\partial \ell} \\
+ k(\theta - v) \frac{\partial \hat{C}}{\partial v} + \frac{1}{2} v \frac{\partial^2 \hat{C}}{\partial \ell^2} + \rho \sigma v \frac{\partial^2 \hat{C}}{\partial \ell \partial v} + \frac{1}{2} \sigma^2 v \frac{\partial^2 \hat{C}}{\partial v^2} - r \hat{C} \\
+ \lambda \int_{-\infty}^{\infty} \left( \hat{C}(\ell + q, v, t) - \hat{C}(\ell, v, t) \right) \phi_Q(q) dq,
\]

(5)

and by substituting and separating variables, produce:

• **PIDE for \( P_1 \)**, with boundary condition \( \hat{P}_1(\ell, v, T; \kappa, T) = 1_{\ell > \kappa} \):

\[
0 = \frac{\partial \hat{P}_1}{\partial t} + A_1[\hat{P}_1](\ell, v, t; \kappa, T) \equiv \frac{\partial \hat{P}_1}{\partial t} + A[\hat{P}_1](\ell, v, t; \kappa, T) + v \frac{\partial \hat{P}_1}{\partial \ell} \\
+ \rho \sigma v \frac{\partial \hat{P}_1}{\partial v} + (r - \lambda \bar{J}) \hat{P}_1 + \lambda \int_{-\infty}^{\infty} (e^q - 1) \hat{P}_1(\ell + q, v, t) \phi_Q(q) dq;
\]

(6)

• **PIDE for \( P_2 \)**, with boundary condition \( \hat{P}_2(\ell, v, T; \kappa, T) = 1_{\ell > \kappa} \):

\[
0 = \frac{\partial \hat{P}_2}{\partial t} + A_2[\hat{P}_2](\ell, v, t; \kappa, T) \equiv \frac{\partial \hat{P}_2}{\partial t} + A[\hat{P}_2](\ell, v, t; \kappa, T) + r \hat{P}_2;
\]

(7)
3.2 Characteristic Function:

- Corresponding *characteristic functions defined by Fourier transforms*,

\[ f_j(\ell, v, t; y, T) \equiv - \int_{-\infty}^{\infty} e^{iy\kappa} d\hat{P}_j(\ell, v, t; \kappa, T), \]  

\hspace{1cm} \text{(8)}

- Satisfying the *same PIDEs* as the \( \hat{P}_j(\ell, v, t; \kappa, T) \):

\[ \frac{\partial f_j}{\partial t} + A_j[f_j](\ell, v, t; \kappa, T) = 0, \]  

\hspace{1cm} \text{(9)}

where \( A_j \) represents the corresponding full backward operators in (6) and (7) with boundary conditions, \( f_j(\ell, v, T; y, T) = +e^{iy\ell} \), respectively for \( j = 1 : 2 \).

- **Solution** conjecture:

\[ f_j(\ell, v, t; y, t + \tau) = \exp (g_j(\tau) + h_j(\tau)v + iy\ell + \beta_j(\tau)), \]  

\hspace{1cm} \text{(10)}

with \( \beta_j(\tau) = r\tau \delta_{j,2} \) and BCs \( g_j(0) = 0 = h_j(0) \) for \( j = 1 : 2 \).
3.3 Solution Details:

- For the Fourier transforms $f_j$ for $j = 1 : 2$,

$$
h_j(\tau) = \frac{(\eta_j^2 - \Delta_j^2)(e^{\Delta_j \tau} - 1)}{\sigma^2(\eta_j + \Delta_j - (\eta_j - \Delta_j)e^{\Delta_j \tau})}; \quad (11)
$$

$$
g_j(\tau) = ((r - \lambda \bar{J})iy - \lambda \bar{J}\delta_{j,1} - r\delta_{j,2})\tau
+ \lambda \tau \int_{-\infty}^{\infty} (e^{(iy+\delta_{j,1})q} - 1)\phi_Q(q) dq
- \frac{k\theta}{\sigma^2} \left(2 \ln \left(1 - \frac{(\Delta_j + \eta_j)(1 - e^{-\Delta_j \tau})}{2\Delta_j}\right) + (\Delta_j + \eta_j)\tau\right), \quad (12)
$$

where

$$
\eta_j = \rho\sigma(iy + \delta_{j,1}) - k \quad \& \quad \Delta_j = \sqrt{\eta_j^2 - \sigma^2 iy(iy \pm 1)};
$$

$$
\int_{-\infty}^{\infty} (e^{(iy+1)q} - 1)\phi_Q(q) dq = \frac{e^{(iy+1)b} - e^{(iy+1)a}}{(b - a)(iy + 1)} - 1.
$$
The tail probabilities $P_j$ for $j = 1:2$ are

$$P_j(S(t), V(t), t; K, T) = \frac{1}{2} \tag{13}$$

$$+ \frac{1}{\pi} \int_{0^+}^{+\infty} \text{Re} \left[ \frac{e^{-iy \ln(K)} f_j(\ln(S(t)), V(t), t; y, T)}{iy} \right] dy,$$

by complex integration on equivalent contours yielding a residue of $1/2$ and a principal value integral in the limit to the left of the apparent singularity at $y = 0^+$, since the integrand is bounded in the singular limit.
4. Computing Fourier Integrals and Inverses

4.1 Using 10-point Gauss-Legendre formula for DFTs:

Re-write the Fourier integral as

\[
I(x) = \int_0^\infty F(x) \, dx = \lim_{N \to \infty} \sum_{j=1}^N \int_{(j-1)h}^{jh} F(x) \, dx. \tag{14}
\]

- Because of singularity at \( y = 0 \) and oscillatory behavior, \textit{discrete Fourier transform (DFT)} sub-integrals in (14) are computed by means of a \textit{highly accurate, ten-point Gauss-Legendre formula}, which is also an open formula, not evaluating the function at the endpoints.
- \( N \) is not fixed but determined by a \textit{local stopping criterion}: the integration loop is stopped if the ratio of the contribution of the last strip to the total integration becomes smaller than 0.5e-7.
- Step size \( h = 5 \): Good choice for fast convergence and good precision.
4.2 Using Fast Fourier Transform (FFT):  
(After Carr and Madan (1999))

- **Initial call option price:**

\[
C(S(t), V(t), t; K, T) = -\int_{K}^{\infty} e^{-r(T-t)} (S(t) - K) dP_2(S(t), V(t), t; K, T); \quad (15)
\]

- **Modified call option price to remove the singularity:**

\[
C^{(\text{mod})}(S(t), V(t), t; \kappa, T) = e^{\alpha \kappa} C(S(t), V(t), t; K, T); \quad (16)
\]

- Corresponding Fourier transform of \(C^{(\text{mod})}(S(t), V(t), t; \kappa, T):\)

\[
\Psi(S(t), V(t), t; y, T) = \int_{-\infty}^{\infty} e^{iy\kappa} C^{(\text{mod})}(S(t), V(t), t; \kappa, T) d\kappa; \quad (17)
\]

- Thus,

\[
C(S(t), V(t), t; K, T) = \frac{e^{-\alpha \kappa}}{\pi} \int_{0}^{\infty} e^{-iy\kappa} \Psi(S(t), V(t), t; y, T) dy; \quad (18)
\]
where

\[ \Psi(S(t), V(t), t; y, T) = -\int_{-\infty}^{\infty} e^{iy\kappa} \int_{\kappa}^{\infty} e^{\alpha\kappa} e^{-r(T-t)} (S(t) - K) \]
\[ \cdot dP_2(S(t), V(t), t; \kappa, T) d\kappa \]
\[ = e^{-r(T-t)} f_2(y - (\alpha + 1)i) \quad \frac{\alpha^2 + \alpha - y^2 + i(2\alpha + 1)y}{\alpha^2 + \alpha - y^2 + i(2\alpha + 1)y}, \quad (19) \]

- Transfer the Fourier integral into discrete Fourier transform (DFT) and incorporate Simpson’s rule (Carr and Madan (1999)) to increase accuracy of the \textit{FFT application for Fourier inverses}:

\[ C(S(t), V(t), t; \kappa, T) = \frac{e^{-\alpha\kappa}}{\pi} \sum_{j=1}^{N} e^{-\frac{i}{N} j \kappa} e^{iy_j (L - \ln(S))} \Psi(y_j) \]
\[ \cdot \frac{dy}{3} [3 + (-1)^{(j+1)} - \delta_{j,1}], \quad (20) \]

where \( \alpha = 2.0 \) and \( dy = 0.25 \) are used.
5. Numerical Results for Call and Put Options

- Two numerical algorithms give the same results within accuracy standard. The FFT method can compute different levels strike price near at-the-money (ATM) in 5 seconds. The standard integration method can give out the results for one specific strike price in about 0.5 seconds. The implementations are using MATLAB 6.5 and on the PC with 2.4GHz CPU.
- The option prices from the stochastic-volatility jump-diffusion (SVJD) model are compared with those of Black-Scholes model:

Parameters: \( r = 3\% \), \( S_0 = \$100 \); \( \sigma = 7\% \), \( V = 0.012 \), \( \rho = -0.622 \), \( \theta = 0.53 \), \( k = 0.012 \); \( a = -0.028 \), \( b = 0.026 \), \( \lambda = 64 \).
5.1 Call Option Prices:

(a) Call prices for $T = 0.1$.  (b) Call prices for $T = 0.25$.  (c) Call prices for $T = 1.0$.

Figure 1: Call option prices for the SVJD model compared to the corresponding pure diffusion Black-Scholes values for $T = 0.1, 0.25, 1.0$. 
5.2 Put Option Prices:

(a) Put prices for \( T = 0.1 \).  
(b) Put prices for \( T = 0.25 \).  
(c) Put prices for \( T = 1.0 \).

Figure 2: Put option prices for the SVJD model by put-call parity compared to the corresponding pure diffusion Black-Scholes values for \( T = 0.1, 0.25, 1.0 \).
6. Conclusions

- Proposed an alternative stochastic-volatility, jump-diffusion (SVJD) model, stochastic volatility follows a square-root mean-reverting stochastic process and jump-amplitude has log-uniform distribution.
- Characteristic functions of the log-terminal stock price and the conditional risk neutral probability are analytically derived.
- The option prices are expressed in terms of characteristic functions in formally closed form.
- Two numerical computing algorithms using an accurate 10-point Gauss-Legendre discrete Fourier integral (DFT) formula and a fast FFT are compared. Same option prices are given by two methods for the SVJD model.
- Compared with those from Black-Scholes model, the SVJD model have higher option prices, especially for longer maturity and near at-the-money (ATM) strike price.
