# Outline

- 1 Problem Statement
  - least squares solving
  - graphics processing units
- 2 Accelerated Blocked Householder QR
  - accumulating the Householder reflectors
  - experimental results

## problem statement

Given a linear system  $A\mathbf{x} = \mathbf{b}$ ,  
compute the least squares solution  $\mathbf{x}$ .

The least squares solution minimizes  $\|\mathbf{b} - A\mathbf{x}\|_2^2$ .

Two steps with the QR decomposition:

- 1 Compute the Householder QR factorization:  $A = QR$ .  
The blocked Householder QR [Bischof & Van Loan, 1987] is rich in matrix-matrix multiplications.
- 2 Solve the upper triangular system  $R\mathbf{x} = Q^T\mathbf{b}$ .  
Formulas in [Heller, 1978] are applied recursively in a parallel triangular matrix inversion [Nasri & Mahjoub, 2001].

### *Problem:*

Can acceleration by Graphics Processing Units (GPUs) compensate the cost overhead caused by multiple double precision?

# error analysis of a lower triangular block Toeplitz solver

joint with Simon Telen and Marc Van Barel, in the CASC 2020 proceedings

$$\text{Solving } (A_0 + A_1 t + A_2 t^2 + \cdots + A_i t^i)(x_0 + x_1 t + x_2 t^2 + \cdots + x_i t^i) \\ = (b_0 + b_1 t + b_2 t^2 + \cdots + b_i t^i)$$

leads to a lower triangular block system:

$$\begin{bmatrix} A_0 & & & & \\ A_1 & A_0 & & & \\ A_2 & A_1 & A_0 & & \\ \vdots & \vdots & \vdots & \ddots & \\ A_i & A_{i-1} & A_{i-2} & \cdots & A_0 \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ \vdots \\ x_i \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ \vdots \\ b_i \end{bmatrix}.$$

Let  $\kappa$  be the condition number of  $A_0$ . Let  $\|A_0\| = \|x_0\| = 1$ ,  $\|x_i\| \approx \rho^i$ .  
In our context,  $\rho \approx 1/R$ , where  $R$  is the convergence radius.

If  $\|A_i\| \approx \rho^i$ , then  $\frac{\|\Delta x_i\|}{\|x_i\|} \approx \kappa^{i+1} \epsilon_{\text{mach}}$ , and accuracy is lost.

With multiple double precision, a small  $\epsilon_{\text{mach}}$  gives accurate results.

# multiple double precision — error free transformations

Computing the 2-norm of a vector of dimension 64  
of random complex numbers on the unit circle equals 8.  
Observe the second double of the multiple double 2-norm.

```
double double : 8.000000000000000E+00 - 6.47112461314111E-32
quad double   : 8.000000000000000E+00 + 3.20475411419393E-65
octo double   : 8.000000000000000E+00 - 9.72609915198313E-129
```

  - ▶ The double double arithmetic of CAMPARY performs best for the problem of matrix-vector multiplication.
  - ▶ Concerning quad double precision, *“the CAMPARY library is faster than our implementation; however as the precision increases the execution time of CAMPARY also increases significantly.”*

# Graphics Processing Units (GPUs)

- Data parallel algorithms execute the same Single Instruction on Multiple Data elements (SIMD).
- Memory bandwidth of GPUs is typically ten times higher than the memory bandwidth of CPUs.

## Definition (CGMA ratio)

The *Compute to Global Memory Access (CGMA) ratio* is the number of floating-point calculations performed by a kernel for each access to the global memory.

- The NVIDIA K20C, P100, and V100 are capable of teraflop performance in double precision.

## five different NVIDIA GPUs

| NVIDIA GPU       | CUDA | #MP | #cores/MP | #cores | GHz  |
|------------------|------|-----|-----------|--------|------|
| Tesla C2050      | 2.0  | 14  | 32        | 448    | 1.15 |
| Kepler K20C      | 3.5  | 13  | 192       | 2496   | 0.71 |
| Pascal P100      | 6.0  | 56  | 64        | 3584   | 1.33 |
| Volta V100       | 7.0  | 80  | 64        | 5120   | 1.91 |
| GeForce RTX 2080 | 7.5  | 46  | 64        | 2944   | 1.10 |

The double precision peak performance of the P100 is 4.7 TFLOPS. At 7.9 TFLOPS, the V100 is 1.68 times faster than the P100.

To evaluate the algorithms, compare the ratios of the wall clock times on the P100 over V100 with the factor 1.68.

For every kernel, the number of arithmetical operations is accumulated. The total number of double precision operations is computed using the cost overhead multipliers.

## customized software

The code for the arithmetical operations generated by the CAMPARY software was customized for each precision.

- Instead of representing a quad double by an array of four doubles, all arithmetical operations work on four separate variables, one for each double.

By this customization an array of quad doubles is stored as four separate arrays of doubles and a matrix of quad doubles is represented by four matrices of doubles.

- The `double2` and `double4` types of the CUDA SDK work for double double and quad double, but not for the more general multiple double arithmetic.
- QDlib provides definitions for the square roots and various other useful functions for double double and quad double arithmetic. Those definitions are extended to octo double precision.

# computational algebraic geometry

The lower triangular block Toeplitz matrix originates from the application of Newton's method to compute power series developments of algebraic curves.

Power series are a symbolic-numeric way to solve polynomial systems.

With S. Telen, M. Van Barel: [A Robust Numerical Path Tracking Algorithm for Polynomial Homotopy Continuation](#).

*SIAM Journal on Scientific Computing* 42(6):A3610–A3637, 2020.

Two computational tasks for polynomial homotopy continuation:

- 1 evaluation and differentiation of polynomials (PDSEC 2021),
- 2 solving linear systems (PDSEC 2022).

Both tasks are suitable for acceleration with graphics processing units.

## the blocked Householder QR

Consider a  $3m$ -by- $3n$  tiled matrix,  $m \geq n$ :

$$A = \left[ \begin{array}{c|cc} & & \\ \hline A_{1,1} & A_{1,2} & \\ \hline & A_{2,2} & A_{2,3} \\ \hline & & A_{3,3} \end{array} \right], \quad \begin{array}{l} A_{1,1} \text{ is } 3m\text{-by-}n, \\ A_{1,2} \text{ is } m\text{-by-}2n, \quad A_{2,3} \text{ is } m\text{-by-}n, \\ A_{2,2} \text{ is } 2m\text{-by-}n, \quad A_{3,3} \text{ is } m\text{-by-}n. \end{array}$$

The Householder transformations are accumulated in an orthogonal  $3m$ -by- $3m$  matrix  $Q$ .

The upper triangular reduction  $R$  of  $A$  is written in the matrix  $A$ .

Early GPU implementations:

- Baboulin, Dongarra, and Tomov, TR UT-CS-08-200, 2008
- Kerr, Campbell, and Richards, GPGPU'09 conference
- Volkov and Demmel, Conference on Supercomputing, 2008

# evolution of $Q$ and $R$ , $I$ is the identity matrix

$$\begin{aligned}
 A, Q &= \left[ \begin{array}{c|cc} & A_{1,2} & \\ \hline A_{1,1} & & \\ \hline & A_{2,2} & A_{2,3} \\ \hline & & A_{3,3} \end{array} \right], & \left[ \begin{array}{c|c|c} I & & \\ \hline & I & \\ \hline & & I \end{array} \right] \\
 \rightarrow & \left[ \begin{array}{c|cc} & R_{1,2} & \\ \hline R_{1,1} & & \\ \hline & A_{2,2} & A_{2,3} \\ \hline & & A_{3,3} \end{array} \right], & \left[ \begin{array}{c|c|c} Q_1 & & \\ \hline & I & \\ \hline & & I \end{array} \right] \\
 \rightarrow & \left[ \begin{array}{c|cc} & R_{1,2} & \\ \hline R_{1,1} & & \\ \hline & R_{2,2} & R_{2,3} \\ \hline & & A_{3,3} \end{array} \right], & \left[ \begin{array}{c|c|c} Q_1 & Q_2 & \\ \hline & & \\ \hline & & I \end{array} \right] \\
 \rightarrow & \left[ \begin{array}{c|cc} & R_{1,2} & \\ \hline R_{1,1} & & \\ \hline & R_{2,2} & R_{2,3} \\ \hline & & R_{3,3} \end{array} \right], & \left[ \begin{array}{c|c|c} Q_1 & Q_2 & Q_3 \\ \hline & & \\ \hline & & \end{array} \right].
 \end{aligned}$$

# Householder Reflectors

The Householder reflector  $P$  is represented by a vector  $\mathbf{v}$ :

$$P = I - \beta \mathbf{v} \mathbf{v}^T, \quad \beta = 2 / \mathbf{v}^T \mathbf{v}, \quad P \mathbf{x} = \|\mathbf{x}\|_2 \mathbf{e}_1,$$

where  $\mathbf{x}$  is the current column and  $\mathbf{e}_1 = (1, 0, \dots, 0)^T$ .

The Householder matrices are aggregated in an orthogonal matrix

$$P_{WY} = I + WY^T,$$

where  $Y$  stores the Householder vectors in a trapezoidal shape.  $W$  is defined by the Householder vectors and the corresponding  $\beta$ s.

With this  $WY$  representation, the updates to  $Q$  and  $R$  are

$$\begin{aligned} Q &= Q + Q \star W \star Y^T, \\ R &= R + Y \star W^T \star C, \end{aligned}$$

which involve many matrix-matrix products [Bischof & Van Loan, 1987].

## four stages, several kernels

### Algorithm 2: BLOCKED ACCELERATED HOUSEHOLDER QR.

Input :  $N$  is the number of tiles,  
 $n$  is the size of each tile,  
 $M$  is the number of rows,  $M \geq Nn$ ,  
 $A$  is an  $M$ -by- $Nn$  matrix.

Output :  $Q$  is an orthogonal  $M$ -by- $M$  matrix,  
 $R$  is an  $M$ -by- $Nn$  matrix,  $A = QR$ .

For  $k$  from 1 to  $N$  do

- 1 Compute Householder vectors for one tile, reduce  $R_{k,k}$ .
- 2 Define  $Y$ , compute  $W$  and  $Y \star W^T$ .
- 3 Add  $Q \star YW^T$  to update  $Q$ .
- 4 If  $k < N$ , add  $YW^T \star C$  to update  $R$ .

# Householder QR is cubic in the dimension

The code is written for multiple double precision.

Thanks to the high Compute to Global Memory Access ratios of multiple double precision, entries of a matrix can be loaded directly into the registers of a kernel (bypassing shared memory).

The computation cost is proportional to  $M^3$ , for  $M = Nn$ .  
The hope is to reduce the cost by a factor of  $M$ .

## data staging

A matrix  $A$  of multiple doubles is stored as  $[A_1, A_2, \dots, A_m]$ ,

- $A_1$  holds the most significant doubles of  $A$ ,
- $A_m$  holds the least significant doubles of  $A$ .

Similarly,  $\mathbf{b}$  is an array of  $m$  arrays  $[\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_m]$ , sorted in the order of significance.

In complex data, real and imaginary parts are stored separately.

The main advantages of this representation are twofold:

- 1 facilitates staggered application of multiple double arithmetic,
- 2 benefits efficient memory coalescing, as adjacent threads in one block of threads read/write adjacent data in memory, avoiding bank conflicts.

# experimental setup

About the input matrices:

- Random numbers are generated for the input matrices.
- Condition numbers of random triangular matrices almost surely grow exponentially [Viswanath & Trefethen, 1998].
- In the standalone tests, the upper triangular matrices are the  $U$ s of an LU factorization of a random matrix, computed by the host.

Two input parameters are set for every run:

- The size of each tile is the number of threads in a block.  
The tile size is a multiple of 32.
- The number of tiles equals the number of blocks.  
As the V100 has 80 streaming multiprocessors, the number of tiles is at least 80.

## 2-logarithms of times on the V100 in 3 precisions

For increasing dimensions,  
we expect the time to be multiplied by 8 when the dimension doubles.

Increasing precision, multipliers are 11.7 (2d to 4d) and 5.4 (4d to 8d).

$512 = 4 \times 128$ ,  $1024 = 8 \times 128$ ,  $1536 = 12 \times 128$ ,  $2048 = 16 \times 128$

The performance drops at 2048 in double double precision.

## 2-logarithms of times on 3 GPUs in 3 precisions

Increasing precision, multipliers are 11.7 (2d to 4d) and 5.4 (4d to 8d).

On 8 tiles for size 128:

The observed cost overhead factors are less than the multipliers.  
The heights of the bars follow a regular pattern.

# back substitution in quad double precision on the V100

Arithmetic intensity (1) and kernel time flops (2), for dimensions  $80 \times n$ :

| $n$ | 32    | 64    | 96    | 128   | 160   | 192   | 224    | 256    |

| total wall flops   | 230.8 | 1797.3 | 3144.7 | 3897.0  |

Teraflop performance is attained already in double double precision.

## conclusions

Taking 439, the average number of double operations in the tallies of the operational counts for quad double arithmetic, as the scaling factor, teraflop performance on a GPU can be viewed as 2.2 gigaflops on a single threaded computation.

Using this interpretation, the experiments show that GPU acceleration does compensate the cost overhead of quad double arithmetic.

In any case, the observed cost overhead ratios in going from double double to quad double are less than the ratios predicted by the operational count tallies, thanks to the high CGMA ratios.

The good performance on problems of dimension 1,024 in quad double precision observed on many GPUs should be encouraging to consider the use of multiple double arithmetic in scientific applications.

All code is available under the GPL-3.0 license at
