# Outline

#### Problem Statement

- numerical analytic continuation
- the need for multiple double precision
- software packages QDlib, GQD, and CAMPARY
- convergence and performance

#### Newton for Taylor Series

- monomial and binomial homotopies
- linearization of power series
- staggered computations
- computational results

# scalable polynomial homotopy continuation

towards a scalable polynomial system solver

With homotopy continuation we can track millions of solution paths for systems of polynomial equations in modest dimension.

Goal: track a solution path defined polynomial homotopies in large dimensions, at least 1024 equations and variables.

A polynomial homotopy is a system of polynomials in one parameter t, the solution trajectories are then also analytic functions in t, therefore *apply analytic continuation* to approximate the solutions.

Graphics Processing Units capable of teraflop performance can compensate for the cost overhead caused by quad double arithmetic.

The problems become *compute bound* already with complex double double and quad double arithmetic.

## power series arithmetic

motivation for multiple double precision

$$\exp(t) = \sum_{k=0}^{d-1} \frac{t^k}{k!} + O(t^d).$$

Assuming the quadratic convergence of Newton's method:

k	1/k!	recommended precision	eps
7	2.0e-004	double precision okay	2.2e-16
15	7.7e-013	use double doubles	4.9e-32
23	3.9e-023	use double doubles	
31	1.2e-034	use quad doubles	6.1e-64
47	3.9e-060	use octo doubles	4.6e-128
63	5.0e-088	use octo doubles	
95	9.7e-149	need hexa doubles	5.3e-256
127	3.3e-214	need hexa doubles	

eps is the multiple double precision

## convergence and performance

Two concerns when running Newton's method:

- For which inputs does the method converge?
- Which kernels occupy most of the running time?

Nearby singularities are problematic for convergence.

#### Theorem (the ratio theorem, Fabry 1896)

If for the series 
$$x(t) = c_0 + c_1 t + c_2 t^2 + \dots + c_n t^n + c_{n+1} t^{n+1} + \dots$$

we have 
$$\lim_{n\to\infty} c_n/c_{n+1} = z$$
, then

- z is a singular point of the series, and
- it lies on the boundary of the circle of convergence of the series.

Then the radius of this circle is less than |z|.

The ratio  $c_n/c_{n+1}$  is the pole of Padé approximants of degrees [n/1] (*n* is the degree of the numerator, with linear denominator).

## monomial and binomial homotopies

Consider *n* variables **x**, *A* is an *n*-by-*n* exponent matrix, and **b**(*t*) is a vector of *n* series of order  $O(t^d)$ :

 $\mathbf{x}^{A} = \mathbf{b}(t)$  is a monomial homotopy.

For example, n = 3,  $\mathbf{x} = [x_1, x_2, x_3]$ :

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix} \begin{cases} x_1 = b_1(t) & x_1(t) = \exp(\alpha_1 t) + O(t^d) \\ x_1 x_2 = b_2(t) & x_2(t) = \exp(\alpha_2 t) + O(t^d) \\ x_1 x_2 x_3 = b_3(t) & x_3(t) = \exp(\alpha_3 t) + O(t^d) \end{cases}$$

where  $\exp(\alpha t) + O(t^4) = 1 + \alpha t + \frac{\alpha^2}{2!}t^2 + \frac{\alpha^3}{3!}t^3 + O(t^4)$ , with  $\alpha \in [-1, -1 + \delta] \cup [1 - \delta, 1]$ ,  $\delta > 0$ , or  $|\alpha| = 1$  for random  $\alpha \in \mathbb{C}$ .

 $\mathbf{c}_{A}\mathbf{x}^{A} + \mathbf{c}_{A^{T}}\mathbf{x}^{A^{T}} = \mathbf{b}(t)$  is a binomial homotopy.

## a task graph for a triangular block Toeplitz system

# different types of accelerated computations

- convolutions for evaluation and differentiation
- e Householder QR
- Q<sup>H</sup>b computations
- **④** back substitutions to solve  $R\mathbf{x} = Q^H \mathbf{b}$
- **(a)** updates  $\mathbf{b} = \mathbf{b} A\mathbf{x}$
- **o** residual computations  $\|\mathbf{b} A\mathbf{x}\|_1$

#### Which of the six types occupies most time?

< ロ > < 同 > < 回 > < 回 >

## staggered computations

Computing  $\mathbf{x}(t) = \mathbf{x}_0 + \mathbf{x}_1 t + \mathbf{x}_2 t^2 + \dots + \mathbf{x}_{d-1} t^{d-1}$ , observe:

- Start x<sub>0</sub> with half its precision correct, otherwise Newton's method may not converge.
- 2 Increase *d* in the order  $O(t^d)$  gradually, e.g.: the new *d* is d + 1 + d/2, hoping (at best) for quadratic convergence.
- Once x<sub>k</sub> is correct, the corresponding b<sub>k</sub> = 0, as b<sub>k</sub> is obtained by evaluation, and then the update Δx<sub>k</sub> should no longer be computed because

$$QR\Delta \mathbf{x}_k = \mathbf{b}_k = \mathbf{0} \quad \Rightarrow \quad \Delta \mathbf{x}_k = \mathbf{0}.$$

This gives a criterion to stop the iterations.

# graphics processing units

The code was developed for the "Volta" V100 NVIDIA GPU, and tested on the "Pascal" P100 and RTX 2080 NVIDIA GPUs.

NVIDIA GPU	CUDA	#MP	#cores/MP	#cores	GHz
Pascal P100	6.0	56	64	3584	1.33
Volta V100	7.0	80	64	5120	1.91
GeForce RTX 2080	7.5	46	64	2944	1.10

The double precision peak performance of the P100 is 4.7 TFLOPS. At 7.9 TFLOPS, the V100 is 1.68 times faster than the P100.

To evaluate the algorithms, compare the ratios of the wall clock times on the P100 over V100 with the factor 1.68.

For every kernel, the number of arithmetical operations is accumulated. The total number of double precision operations is computed using the cost overhead multipliers.

-

# doubling precisions, wall clock and kernel times

On one column of monomials, triangular exponent matrix of ones, n = 1024, d = 64, 24 steps, in 4 different precisions, on the V100:

Doubling the precision less than doubles the wall clock time and increases the time spent by all kernels.

## n = 1024, d = 64, 24 steps in octo double precision

Six different types of accelerated computations, on the V100, on one column of monomials and two columns of monomials:
