approximate zeroes

For a function f in one variable x , Newton's method defines

$$x_{k+1} = N_f(x_k), \quad k = 0, 1, \dots \text{ and } N_f(x) = x - \frac{f(x)}{f'(x)},$$

provided the derivative $f'(x_k) \neq 0$ for all k .

z is *an approximate zero for a root ζ of f* ($f(\zeta) = 0$) if

- 1 $x_{k+1} = N_f(x_k)$ is defined for all $k = 0, 1, \dots$ starting with $x_0 = z$; and
- 2 the convergence is quadratic:

$$|x_k - \zeta| \leq \left(\frac{1}{2}\right)^{2^k - 1} |z - \zeta|.$$

Needed: a criterion to determine if z is an approximate zero.

For a criterion to determine if a given number is an approximate zero, we need an auxiliary function

$$\gamma : \mathbb{C}[\mathbf{x}] \times \mathbb{C} \rightarrow \mathbb{R}$$

$$(f, \mathbf{x}) \mapsto \gamma(f, \mathbf{x}) = \max_{k=2}^{\deg(f)} \left| \frac{f^{(k)}(\mathbf{x})}{k! f'(\mathbf{x})} \right|^{1/(k-1)}$$

where $f^{(k)}$ is the k th derivative of f .

Note: $\gamma(f, \mathbf{x})$ is undefined for $f'(\mathbf{x}) = 0$.

Example: $\gamma(x^3 - 1, x) = \max \left(\left| \frac{6x}{2! \cdot 3x^2} \right|, \left| \frac{6}{3! \cdot 3x^2} \right|^{1/2} \right)$
is defined for all $x \neq 0$.

Newton's method in
projective space

If we know the exact root ζ , then a criterion is below.

Theorem 1

Assume $f(\zeta) = 0$ and $f'(\zeta) \neq 0$.

If $|x - \zeta| \leq \frac{3 - \sqrt{7}}{2\gamma(f, \zeta)}$, then x is an approximate zero for ζ .

The number $\frac{3 - \sqrt{7}}{2\gamma(f, \zeta)}$ defines the radius of a disk

- in the complex plane, centered at ζ
- for which Newton's method converges quadratically.

To determine whether x is an approximate zero for f :

Theorem 2

There is a universal constant α_0 :

if $\alpha(f, x) < \alpha_0$ then

- *x is an approximate zero for a root ζ of f and*
- *$|x - \zeta| \leq 2\beta(f, x)$.*

In [Blum, Cucker, Shub, Smale 1998], the best value for $\alpha_0 = \frac{1}{4}(13 - 3\sqrt{17}) \approx 0.157671$.

Consider

$$f(\mathbf{x}) = \begin{cases} x_1 - \alpha = 0 \\ x_2 - x_1^2 = 0 \\ x_3 - x_2^2 = 0 \\ x_4 - x_3^2 = 0 \end{cases}$$

where α is a parameter, with $(\alpha, \alpha^2, \alpha^4, \alpha^8)$ as solution.

Although $f(\mathbf{x}) = \mathbf{0}$ consists only of quadrics,
for $\alpha < 1$ or $\alpha > 1$, the solution decreases or increases.

The telescoping poses challenges for numerical methods.

Lemma 3

For a polynomial f in x , $\deg(f) = d$, $f(\zeta) = 0$, $f'(\zeta) \neq 0$, we have:

$$|N_f(x) - \zeta| \leq \left(\frac{u}{1 - 4u + 2u^2} \right) |x - \zeta|,$$

for

$$u = \gamma(f, \zeta) |x - \zeta| < 1 - \frac{\sqrt{2}}{2}.$$

Proof. We need to show $\left| \frac{f'(\zeta)}{f(x)} \right| \leq \frac{(1-u)^2}{1-4u+2u^2}$.

 \end{aligned}$$

estimating $f'(\zeta)/f'(x)$

$$\left| \frac{f'(\zeta)}{f'(x)} \right| = \frac{1}{|1+B|} \leq \sum_{k=0}^{\infty} |B|^k = \frac{1}{1-|B|},$$

provided $|B| < 1$. Therefore we estimate $|B|$:

$$|B| \leq \sum_{k=2}^d ku^{k-1} = \sum_{k=1}^d ku^{k-1} - 1 \leq \sum_{k=1}^{\infty} ku^{k-1} - 1 = \frac{1}{(1-u)^2} - 1.$$

To verify whether $|B| < 1$ we solve $\frac{1}{(1-u)^2} - 1 = 1$.

The smallest positive root of $1 - 4u + 2u^2$ is $1 - \frac{\sqrt{2}}{2}$,
so $u < 1 - \frac{\sqrt{2}}{2} \Rightarrow |B| < 1$. Thus:

$$\left| \frac{f'(\zeta)}{f'(x)} \right| \leq \frac{1}{1 - \left(\frac{1}{(1-u)^2} - 1 \right)} = \frac{(1-u)^2}{1 - 4u + 2u^2}$$

Theorem 1

Assume $f(\zeta) = 0$ and $f'(\zeta) \neq 0$.

If $|x - \zeta| \leq \frac{3 - \sqrt{7}}{2\gamma(f, \zeta)}$, then x is an approximate zero for ζ .

Proof. For x to be an approximate zero of f for the root ζ we must have $|N_f(x) - \zeta| \leq \frac{1}{2}|x - \zeta|$.

Applying Lemma 3, we consider $\frac{u}{1 - 4u + 2u^2} = \frac{1}{2}$.

This equation has two positive solutions: $(3 \pm \sqrt{7})/2$.

We take the smallest solution as a bound for

$$u = \gamma(f, \zeta)|x - \zeta| \leq \frac{3 - \sqrt{7}}{2},$$

which leads to the criterion $|x - \zeta| \leq (3 - \sqrt{7})/(2\gamma(f, \zeta))$. \square

Newton's method in
projective space

Consider $f(\mathbf{x}) = \mathbf{0}$ with $\mathbf{x} = [x_0 : x_1 : x_2 : \cdots : x_n] \in \mathbb{P}^n$.

We have n equations in $n + 1$ variables. For uniqueness, restrict Newton's method to the tangent space $T_{\mathbf{x}}$ at \mathbf{x} :

$$T_{\mathbf{x}} = \{ \mathbf{y} \in \mathbb{P}^{n+1} \mid x_0 y_0 + x_1 y_1 + x_2 y_2 + \cdots + x_n y_n = 0 \}.$$

Denote the inverse of the Jacobian matrix J_f of f restricted to $T_{\mathbf{x}}$ by $J_f(\mathbf{x})|_{T_{\mathbf{x}}}^{-1}$.

The Newton operator in \mathbb{P}^n is $N_f(\mathbf{x}) = \mathbf{x} - J_f(\mathbf{x})|_{T_{\mathbf{x}}}^{-1} f(\mathbf{x})$.

an example

Consider

$$f(x_1, x_2) = \begin{cases} x_1 x_2 - 1 = 0 \\ x_1^2 - 0.002 = 0 \end{cases}$$

where smaller values for 0.002 lead to larger values for x_2 .

In \mathbb{P}^2 : we have $h_1(\mathbf{z}) = z_1 z_2 - z_0^2$ and $h_2(\mathbf{z}) = z_1^2 - 0.002 z_0^2$.

The linear system we solve to compute the update $\Delta \mathbf{z}$ is

$$\begin{bmatrix} -2z_0 & z_2 & z_1 \\ -0.004z_0 & 2z_1 & 0 \\ z_0 & z_1 & z_2 \end{bmatrix} \Delta \mathbf{z} = \begin{bmatrix} h_1(\mathbf{z}) \\ h_2(\mathbf{z}) \\ 0 \end{bmatrix}.$$

For this small example, compute coordinates for \mathbf{z} as

- $x_1 = \sqrt{0.002}$ and $x_2 = 1/\sqrt{0.002}$;
- take for $z_0 = 1/\max(x_1, x_2)$.

With higher working precision, $\mathbf{z} + \Delta \mathbf{z}$ will be more accurate.

Newton's method in projective space

We looked at the region of convergence of Newton's method which led to the notion of approximate roots.

Exercises:

- 1 Consider formula $|x_k - \zeta| \leq \left(\frac{1}{2}\right)^{2^k - 1} |z - \zeta|$ for an approximate zero z close enough to a zero ζ of f . Assuming $|z - \zeta| \leq 0.1$ and given some $\epsilon > 0$, derive a bound on k , the number of iterations so that $|x_k - \zeta| \leq \epsilon$. Illustrate your bound with numerical examples.
- 2 Define a Maple function to evaluate γ for any polynomial f at any point x . Instead of Maple you may also use another computer algebra system.

- 4 Suppose that ζ_1 and ζ_2 are two regular roots of f , i.e.: $f(\zeta_1) = 0 = f(\zeta_2)$ and $f'(\zeta_1) \neq 0 \neq f'(\zeta_2)$. Show that ζ_1 and ζ_2 are separated as follows:

$$|\zeta_1 - \zeta_2| \geq \frac{5 - \sqrt{17}}{4\gamma(f, \zeta_2)}.$$

- 5 Use a computer algebra package to write a procedure to perform one step of the projective Newton method. On input are the polynomials in the system $f(\mathbf{x}) = \mathbf{0}$ with an approximate solution in the original affine coordinates. The procedure performs the transformation to projective coordinates \mathbf{z} , computes the extended Jacobian matrix and solves a linear system for $\Delta\mathbf{z}$. On return is the updated solution in projective and affine coordinates.
