Some
problems

An abstract elementary class is a concrete category.

Grossberg and Shelah noted a category theoretic interpretation in 1983. The formulation that follows is basically due to Kirby.

The Category Str

Objects in str are all structures in a vocabulary τ .
 $\text{str}(A, B)$ is the set of τ -embeddings from A into B .

The category (\mathbf{K}, mod)

The objects of \mathbf{K} are a class of τ -structures

- 1 $\text{mod}(A, B) \subseteq \text{str}(A, B)$
- 2 If $f \in \text{mod}(A, B)$ and $g \in \text{mod}(C, B)$ and $h \in \text{str}(A, C)$ with $f = gh$ then $h \in \text{mod}(A, C)$.
- 3 mod is closed under direct limit and the mod -direct limit is the str -direct limit.
- 4 There is a cardinal $\text{LS}(\mathbf{K})$ such if $f \in \text{str}(A, B)$ and $B \in \mathbf{K}$, there is a $C \in \mathbf{K}$ with $|C| \leq |A| + \kappa$ and $g \in \text{str}(A, C)$ and $h \in \text{mod}(C, B)$ with $f = hg$.

$L_{\omega_1, \omega}(Q)$ as an AEC

Fails union of chains under natural elementary submodel

\leq^*

Require that 'small' definable sets do not grow.
Gives an AEC with LN \aleph_1 .

Weak models

The class of 'weak models' with \leq^* gives an AEC with LN \aleph_0 .
But we added models and argument showing the existence of many models don't work (they might be weak models).

Approaches to $L_{\omega_1, \omega}(Q)$

More concrete version.

A3. If $\langle A_i : i < \delta \rangle$ is a continuous $\prec_{\mathbf{K}}$ -increasing chain:

- 1 $\bigcup_{i < \delta} A_i \in \mathbf{K}$;
- 2 for each $j < \delta$, $A_j \prec_{\mathbf{K}} \bigcup_{i < \delta} A_i$;
- 3 if each $A_i \prec_{\mathbf{K}} M \in \mathbf{K}$ then $\bigcup_{i < \delta} A_i \prec_{\mathbf{K}} M$.

THE PRESENTATION THEOREM

Every AEC is a PCF

More precisely,

Theorem

If K is an AEC with Löwenheim number $\text{LS}(\mathbf{K})$ (in a vocabulary τ with $|\tau| \leq \text{LS}(\mathbf{K})$), there is a vocabulary τ' , a first order τ' -theory T' and a set of $2^{\text{LS}(\mathbf{K})}$ τ' -types Γ such that:

$$\mathbf{K} = \{M' \upharpoonright L : M' \models T' \text{ and } M' \text{ omits } \Gamma\}.$$

Moreover, if M' is an L' -substructure of N' where M', N' satisfy T' and omit Γ then
$$M' \upharpoonright L \prec_{\mathbf{K}} N' \upharpoonright L.$$

This theorem needs A.3.3.

What's so great about PCF

Amalgamation

Galois Types

Tameness

\perp_N

Some
problems

PCF gives:

- Ehrehfeucht Mostowski models;
- omitting types (for Galois types);
- can construct non-splitting extensions;
- key to finding showing a sentence of $L_{\omega_1, \omega}(Q)$ that is categorical in \aleph_1 has a model in \aleph_2 .

But *PCF* classes may not be closed under unions of chains and there even a *PC*-class with both the categoricity and non-categoricity spectrum cofinal in the cardinals.

AMALGAMATION PROPERTY

The class \mathbf{K} satisfies the λ -*amalgamation property* if for any situation with $A, M, N \in \mathbf{K}_\lambda$:

there exists an N_1 such that

Finite Diagrams

If T is a first order theory \mathbf{K} is the class of models of T that omit a certain set Γ of finite-types over the empty set then \mathbf{K} under first order elementary submodel is called a **finite diagram**.

Atomic Classes

If Γ is all non-principal types, \mathbf{K} is called an atomic class.

Homogenous Model Theory

is the study of finite diagrams that admit amalgamation over **SETS**.

(Baldwin, Lachlan, Marker)

Let G be an expansion of a group and let π map X onto G .

Add to the language a binary function $t : G \times X \rightarrow X$ for the fixed-point free action of G on $\pi^{-1}(g)$ for each $g \in G$.

That is, we represent $\pi^{-1}(g)$ as $\{ga : g \in G\}$ for some a with $\pi(a) = g$. This action of G is strictly 1-transitive. This guarantees that each fiber has the same cardinality as G .

π guarantees the number of fibers is the same as $|G|$.

Since there is no interaction among the fibers, categoricity in all uncountable powers follows if G is categorical.

Definition

We say A is a *Whitehead group* if $\text{Ext}(A, \mathcal{Z}) = 0$. That is, every short exact sequence

$$0 \rightarrow \mathcal{Z} \rightarrow H \rightarrow A \rightarrow 0,$$

splits or in still another formulation, H is the direct sum of A and \mathcal{Z} .

Side question: Under $V=L$, Whitehead groups are free; hence PCF. What about in ZFC?

Definition

1 $\perp N = \{A : \text{Ext}^i(A, N) = 0 : i < \omega\}$

2 For $A \subseteq B$ both in $\perp N$, $A \prec_N B$ if $B/A \in \perp N$.

Generalizes the class of Whitehead groups: $\text{Ext}(G, \mathcal{Z}) = 0$.

Baldwin, Eklof, Trlifaj :

Theorem

- 1 For any module N , if the class $(\perp N, \prec_N)$ is an abstract elementary class then N is a cotorsion module.
- 2 For any R -module N , over a ring R , if N is a pure-injective module then the class $(\perp N, \prec_N)$ is an abstract elementary class.
- 3 For an abelian group N , (module over a Dedekind domain R), the class $(\perp N, \prec_N)$ is an abstract elementary class if and only if N is a cotorsion module.

An Interesting detail

We do not know exactly the rings for which the hypothesis of N cotorsion is sufficient for **A.3(3)**. It is sufficient when R is a Dedekind domain:

Lemma

Let R be a Dedekind domain and N a module. Then the following are equivalent:

- 1 N is cotorsion;
- 2 ${}^{\perp}N = {}^{\perp}PE(N)$ where $PE(N)$ denotes the pure-injective envelope of N ;
- 3 ${}^{\perp}N$ is closed under direct limits;
- 4 **A3(3)** holds for $({}^{\perp}N, \prec_N)$.

3) concludes closure under limits of **all** homomorphisms.

The number of models in \aleph_1 : $L_{\omega,\omega}$

Theorem

If a first order theory is a counterexample to the Vaught conjecture then it has 2^{\aleph_1} models of cardinality \aleph_1 .

Proof outline

This is easy from two difficult theorems:

Theorem (Shelah)

If a first order T is not ω -stable T has 2^{\aleph_1} models of cardinality \aleph_1 .

This argument uses many descriptive set theoretic techniques. See Shelah's book [?] or Baldwin's paper [?].

Theorem (Shelah)

An ω -stable first order theory satisfies Vaught's conjecture.

Does the previous theorem extend to $L_{\omega_1, \omega}$?

Keisler showed:

Theorem

For any $L_{\omega_1, \omega}$ -sentence ψ and any fragment L^ containing ψ , if ψ has fewer than 2^{\aleph_1} models of cardinality \aleph_1 then for any $M \models \psi$ of cardinality \aleph_1 , M realizes only countably many L^* -types over the empty set*

Shelah observed that Theorem ?? implies:

Fact

*$(2^{\aleph_0} < 2^{\aleph_1})$ If a **complete** sentence $\psi \in L_{\omega_1, \omega}$ is not ω -stable it has 2^{\aleph_1} models of cardinality \aleph_1 .*

Theorem (Shelah technique)

If an atomic class is ω -stable and has a model in \aleph_1 it has one in \aleph_2 .

Modify Hjorth's construction by replacing Fraïssé with Hrushovski to get:

An ω -stable atomic class characterizing \aleph_2 .

Downward Categoricity

Theorem (Shelah)

*If \mathbf{K} is categorical in λ^+ and satisfies
amalgamation and joint embedding with $\lambda \geq H_2$ then \mathbf{K} is
categorical on $[H_2, \lambda)$.*

What about non-successor cardinals for the hypothesis?

What is the best lower bound?

Is it $\aleph_1, \aleph_\omega, \beth_{\omega_1}, H_2 = \beth_{(\beth_{\omega_1})^+}$?

Necessity of hypotheses

Fact. If \mathbf{K} has amalgamation and is categorical in κ above H_1 , then $\mathbf{K}_{\geq\kappa}$ has jep.

But it is easy to construct sentences ϕ_α of $L_{\omega_1,\omega}$ that are categorical in κ iff $\kappa \geq \beth_{\alpha} \text{Alpha}$.
