The Stability spectrum for classes of atomic models

Abstract

We prove two results on the stability spectrum for $L_{\omega_1,\omega}$. Here $S_i^m(M)$ denotes an appropriate notion (at or mod) of Stone space of *m*-types over *M*. Theorem A. (unstable case) Suppose that for some positive integer *m* and for every $\alpha < \delta(T)$, there is an $M \in \mathbf{K}$ with $|S_i^m(M)| > |M|^{\Box_\alpha(|T|)}$. Then for every $\alpha \geq |T|$, there is an $M \in \mathbf{K}$ with $|S_i^m(M)| > |M| = \lambda$. Theorem B. (strictly stable case) Suppose that for every $\alpha < \delta(T)$, there is $M_\alpha \in \mathbf{K}$ such that $\lambda_\alpha = |M_\alpha| \geq \Box_\alpha$ and $|S_i^m(M_\alpha)| > \lambda_\alpha$. Then for any μ with $\mu^{\aleph_0} > \mu$, \mathbf{K} is not *i*-stable in μ . These results provide a new kind of sufficient condition for the unstable case and shed some light on the spectrum of strictly stable theories in this context. The methods avoid the use of compactness in the theory under study. In the Section 4, we expound the construction of tree indiscernibles for sentences of $L_{\omega_1,\omega}$. Further we provide some context for a number of variants on the Ehrenfeucht-Mostowski construction.

1 Context

For many purposes, e.g., the study of categoricity in power, the class of models of a sentence ϕ of $L_{\omega_1,\omega}$ can be profitably translated to the study of the class of models of a first order theory T that omit a collection Γ of first order types over the empty set. In particular, if ϕ is complete (i.e. a Scott sentence) Γ can be taken as the collection of all non-principal types and the study is of the atomic models of T. This translation dates from the 60's; it is described in detail in Chapter 6 of [Bal09]. The study of finite

^{*}We give special thanks to the Mittag-Leffler Institute where this research was conducted. This is paper 959 in Shelah's bibliography. Baldwin was partially supported by NSF-0500841. Shelah thanks the Binational Science Foundation for partial support of this research.

diagrams (see below) is equivalent to studying sentences of $L_{\omega_1,\omega}$; the study of atomic models of a first order theory is equivalent to studying *complete* sentences of $L_{\omega_1,\omega}$.

The stability hierarchy provides a crucial tool for first order model theory. Shelah [She78] and Keisler [Kei76] show the function $f_T(\lambda) = \sup\{|S(M)| : |M| =$ $\lambda, M \models T$ has essentially only six possible behaviors (four under GCH). In [She70], Shelah establishes a similar result for homogeneous finite diagrams. The homogeneity assumption is tantamount to assuming amalgamation over all sets. This is a strong hypothesis that is avoided in Shelah's further investigation of categoricity in $L_{\omega_1,\omega}$ ([She83a, She83b]), which is expounded as Part IV of [Bal09]. Important examples, due to Marcus and Zilber, which do not satisfy the homogeneity hypothesis are also described in [Bal09]. As we explain below, this investigation begins by identifying the appropriate notion of type over a set (and thus of ω -stability). Shelah [She83a, Bal09] showed that ω -stability implies stability in all powers. And assuming $2^{\aleph_0} < 2^{\aleph_1}$, ω -stability was deduced from \aleph_1 -categoricity. But further questions concerning the stability hierarchy for this notion of type for arbitrary sentences of $L_{\omega_1,\omega}$ had not been investigated. We do so now. In fact our results hold for *arbitrary finite diagrams*, the class of models of first order theory that omit a given set of types over the empty set. But our results are by no means as complete as in homogeneous case.

There are (at least) two *a priori* reasonable notions of Stone space for studying atomic models of a first order theory. (As noted, we could more generally replace 'atomic' by 'finite diagram'.) Recall that for a first order theory T (with a monster model \mathbb{M}) $A \subset \mathbb{M}$ is an *atomic set* if each finite sequence from A realizes a principal type over the empty set. An atomic set is an *atomic model* if it is also a model of the theory T.

Definition 1.1 Let K be the class of atomic models of a complete first order theory.

- 1. Let A be an atomic set; $S_{at}(A)$ is the collection of $p \in S(A)$ such that if $a \in \mathbb{M}$ realizes p, Aa is atomic.
- 2. Let A be an atomic set; $S_{\text{mod}}(A)$ is the collection of $p \in S(A)$ such that p is realized in some $M \in \mathbf{K}$ with $A \subseteq M$.

In [Bal09] we wrote S^* for the notion called S_{mod} here. The latter notation is more evocative. We will simultaneously develop the results for both notions of Stone space and indicate the changes required to deal with the two cases. We will write $S_i(M)$ where *i* can be either at or mod.

We sometimes write |T| for $|\tau|$ where τ is the vocabulary of T. $K = K_T$ is the class of atomic models of T. We write $H = H(\mu)$ for the Hanf number for atomic models of all theories with $|T| = \mu$. By [She78] H equals $\beth_{\delta(T)}$, where $\delta(T)$, the well-ordering number of the class of models of a theory T omitting a family of types, is defined in VII.5 of [She78]. It is also shown there that if T is countable, H evaluates as \beth_{ω_1} while for uncountable $T H = \beth_{(2^{|T|})^+}$. Fix $\mu_{\alpha} = \beth_{\alpha}(|T|)$.

Remark 1.2 In [She70], Shelah's definition of stability makes a stronger requirement; it implies *by definition* the existence of homogeneous models in certain cardinals. We do not make that assumption here so we are considering a larger class of theories.

Definition 1.3 1. *K* is *i*-stable in λ (for i = at or mod) if for every $m < \omega$, and $M \in \mathbf{K}$ with $|M| = \lambda$, $|S_i^m(M)| = \lambda$.

- 2. Stability classes. For either i = at or mod,
 - (a) K is *i*-stable if it is *i*-stable in some λ .
 - (b) **K** is *i*-superstable if it is *i*-stable in all $\lambda \ge H$.
 - (c) **K** is strictly *i*-stable if it is *i*-stable but not *i*-superstable.

For any M, $S_{\rm at}(M)$ contains $S_{\rm mod}(M)$ so at-stability in λ implies mod-stability in λ . Thus for both notions ω -stability implies stability in all powers by results of [She83a, She83b], expounded in [Bal09].

We prove Theorem A in Section 2 and Theorem B in Section 3. The proof of Theorem B uses an application of omitting types in Ehrenfeucht-Mostowski models generated by trees of the form ${}^{<\omega}\lambda$. This is by no means new technology but we weren't able to locate an explicit statement of the result so we include a proof in Section 4.

We acknowledge helpful discussions with Tapani Hyttinen, Ali Enayat, Alexei Kolesnikov, and Lynn Scow.

2 Unstable K

We first show that if there are cardinals λ_{α} in which K is 'sufficiently unstable', then K is not stable in any cardinal.

Theorem 2.1 Suppose that for some positive integer m and for every $\alpha < \delta(T)$, there is an $M_{\alpha} \in \mathbf{K}$ with $|S_i^m(M_{\alpha})| > |M_{\alpha}|^{\square_{\alpha}(|T|)}$. Then for every $\lambda \ge |T|$, there is an M with $|S_i^m(M)| > |M| = \lambda$.

Remark 2.2 (Proof Sketch) Before the formal proof we outline the argument. We start with a sequence of models M_{α} and many distinct types over each of them. By an argument which is completely uniform in α , we construct triples $\langle a_{\alpha,i}, \mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i} \rangle$ for $i < \mu_{\alpha}^+$ with the $a_{\alpha,i}, \mathbf{b}_{\alpha,i} \in M_{\alpha}$ and $\mathbf{d}_{\alpha,i}$ in an elementary extension M'_{α} of M_{α} of the same cardinality and so that $M_{\alpha}\mathbf{d}_{\alpha,i}$ is atomic and the distinctness of the types of the $\mathbf{d}_{\alpha,i}$ is explicitly realized by formulas. Then we apply Morley's omitting types theorem to the M'_{α} and extract from this sequence a countable sequence of order indiscernibles with desirable properties. Finally, this set of indiscernibles easily yields models of all cardinalities with the required properties.

Remark 2.3 The idea of the proof can be seen by ignoring the α and proving a slightly weaker result from one model of size $\beth_{\delta(T)}$.

Notation 2.4 $\lambda_{\alpha} = |M_{\alpha}|^{\beth_{\alpha+2}(|T|)}; \mu_{\alpha} = \beth_{\alpha}(|T|); \kappa_{\alpha} = \beth_{\alpha+2}(|T|).$

Lemma 2.5 There is Φ , proper for linear orders, in a vocabulary τ_{Φ} extending τ with $|\tau_{\Phi}| = |\tau|$, with fixed additional unary predicates P, P_1 and binary R such that:

- 1. For every linear ordering I, $N_I = EM_{\tau}(I, \Phi) \models T$ and $M_I = EM_{\tau}(I, \Phi) \upharpoonright P \in \mathbf{K}$. Naturally, $J \subset I$ implies $N_J \prec N_I$ and $M_J \prec M_I$.
- 2. The skeleton of N_I is $\langle \mathbf{a}_i \mathbf{\hat{b}}_i \mathbf{\hat{c}}_i : i \in I \rangle$ and $\lg(\mathbf{c}_i) = m$.
- *3.* For some first order ϕ :

$$N_I \models (\phi(\mathbf{c}_t, \mathbf{a}_s) \equiv \phi(\mathbf{c}_t, \mathbf{b}_s)) \text{ iff } s <_I t.$$

- 4. $M_I \cup \mathbf{c}_i \subset N_I$ and is atomic.
- 5. For $S_{\text{mod}}(M)$, we add the requirement that for each $s \in I$,

$$M_{I,s} = N_I \upharpoonright \{d : N_I \models R(d, \mathbf{c}_s)\}$$

is an atomic elementary submodel of N_I containing $M_I \mathbf{c}_s$.

Proof. The proof of Lemma 2.5 requires a number of steps. Fix for each $\alpha < \delta(T)$, $M_{\alpha} \in \mathbf{K}$ with $|M_{\alpha}| = \lambda_{\alpha}$ such that $|S_i^m(M_{\alpha})| > \lambda_{\alpha} = |M_{\alpha}|^{\square_{\alpha+2}(|T|)}$. Fix $p_{\alpha,i}$ for $i < \lambda_{\alpha}^+$, a list of distinct types in $S_i^m(M_{\alpha})$. We work throughout in a monster model \mathbb{M} of T.

Notation 2.6 In the following construction, we choose by induction triples $\langle \mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i} \rangle$ for $i < \mu_{\alpha}^+$. We use the following notation for initial segments of the sequences.

- 1. $D_{\alpha,i} = \{ \mathbf{d}_{\alpha,j} : j < i \}.$
- 2. $X_{\alpha,i} = \{ a_{\alpha,i}, \mathbf{b}_{\alpha,i} : j < i \}.$
- *3.* $q_{\alpha,i}$ is the type of $\mathbf{d}_{\alpha,i}$ over $X_{\alpha,i}$.

The following variant on splitting is crucial to carry out the construction. We call it ex-splitting (for external) because the elements which exemplify splitting are required to satisfy the same type over a set D which is not in (so external to) the model M and, in particular, is not required to be realized in an atomic set.

Definition 2.7 Let M be a model, $X \subset M$ and $D \subset \mathbb{M}$. We say that $p \in S_i^m(M)$ ex-splits over (D, X) if there exist $\mathbf{a}, \mathbf{b} \in M, \mathbf{f} \in \mathbb{M}$ so that \mathbf{f} realizes $p \upharpoonright X$, $\mathbf{a} \equiv_D \mathbf{b}$ but (\mathbf{a}, \mathbf{f}) and (\mathbf{b}, \mathbf{f}) realize different types over \emptyset .

We will apply the next claim to M_{α} , $X_{\alpha,i}$, and $D_{\alpha,i}$ when carrying out the construction in paragraph 2.10. Note that this computation does not depend on |M|.

Claim 2.8 For any model M, the number of types in $S_i^m(M)$ that do not ex-split over a pair (D, X) with $|X| = |D| \le \mu_{\alpha}$ is at most $\mu_{\alpha+2}$.

Proof. Let P denote the collection of $tp(\mathbf{e}/M)$ with $lg(\mathbf{e}) = m$ that do not exsplit over a pair (D, X). Each type r in P is determined by knowing $r \upharpoonright X$ and for each formula $\phi_i(x_1, \ldots x_{k_i})$ for i < |T| the restriction of r to one k_i -tuple from each equivalence class of the equivalence relation E_k on M defined by $\mathbf{a}E_{k_i}\mathbf{b}$ if a and b realize the same k_i -type over D. So, since $|D| = \mu_{\alpha}$, there are at most

$$2^{\mu_{\alpha}} \times (2^{2^{|D|}})^{|T|} = (2^{2^{\mu_{\alpha}}})^{|T|} = \mu_{\alpha+2}$$

possible such r.

 $\square_{2.8}$

As noted, for each M_{α} we will be constructing by induction on $i < \mu_{\alpha}^+$, sets $X_{\alpha,i}, D_{\alpha,i}$ of cardinality μ_{α} . We need to choose in advance a type p_{α} which does not ex-split over any $(X_{\alpha,i}, D_{\alpha,i})$ that arises. In order to do that we restrict the source of $D_{\alpha,i}$; clearly $X_{\alpha,i} \subset M_{\alpha}$. That is, we will fix M'_{α} with $M_{\alpha} \prec M'_{\alpha}, |M'_{\alpha}| = \lambda_{\alpha}$ and M'_{α} is μ_{α}^+ -saturated and choose $D_{\alpha,i} \subset M'_{\alpha}$. (Note then that M'_{α} is not in general atomic.)

The number of types in $S_i^m(M_\alpha)$ that do not ex-split over *any* pair (D, X) with $|X| = |D| = \beth_\alpha$ is bounded by the number of such sets, $|M'_\alpha|^{\mu_\alpha}$, times the number of types in $S_i^m(M_\alpha)$ that do not ex-split over a particular choice of (D, X), which is $\mu_{\alpha+2}$ by Claim 2.8. That is, the bound is $|M'_\alpha|^{\mu_\alpha} \times \mu_{\alpha+2}$. Since this number is less than λ^+_α , we can fix a type $p_\alpha \in S_i^M(M_\alpha)$ which does not ex-split over any of the relevant (D, X).

Definition 2.9 For each $\alpha < \delta(T)$, fix M'_{α} with $M_{\alpha} \prec M'_{\alpha}$, $|M'_{\alpha}| = \lambda_{\alpha}$, and M'_{α} is μ^{+}_{α} saturated. Choose, by induction on $i < \mu^{+}_{\alpha}$, triples $\mathbf{e}_{\alpha,i} = \langle \mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i} \rangle$ where

- a) $\mathbf{d}_{\alpha,i} \in M'_{\alpha}$.
- b) $\mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}$ are sequences of the same length from M_{α} that realize the same type over $D_{\alpha,i} = {\mathbf{d}_{\alpha,j} : j < i}$.
- c) The types over the empty set of $(\mathbf{a}_{\alpha,i}, \mathbf{d}_{\alpha,i})$ and $(\mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i})$ differ.
- d) $q_{\alpha,i} = p_{\alpha} \upharpoonright X_{\alpha,i} = \operatorname{tp}(\mathbf{d}_{\alpha,i}/X_{\alpha,i})$ so if $j < i, q_{\alpha,j} \subseteq q_{\alpha,i}$.
- e) $M_{\alpha}\mathbf{d}_{\alpha_i}$ is an atomic set for each *i*. (In the mod-version $N_{\alpha,i}$ is an atomic model containing $M_{\alpha}\mathbf{d}_{\alpha_i}$.)

Construction 2.10 Choose $\mathbf{d}_{\alpha,i}$ to realize $p_{\alpha} \upharpoonright X_{\alpha,i}$. By Claim 2.8 and since $|S_i(M_{\alpha})| > \lambda_{\alpha}$ we can choose $\mathbf{a}_{\alpha,i}$ and $\mathbf{b}_{\alpha,i}$ to satisfy conditions b) and c). So we have

$$\operatorname{tp}(\mathbf{d}_{\alpha,i}, \boldsymbol{a}_{\alpha,j}) = \operatorname{tp}(\mathbf{d}_{\alpha,i}, \mathbf{b}_{\alpha,j}) \text{ if and only if } i < j.$$
(1)

We want this order condition for a single formula. For each $i < \mu_{\alpha}^+$, the types of $(a_{\alpha,i}, \mathbf{d}_{\alpha,i})$ and $(\mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i})$ differ. That is, $\phi_{\alpha,i}(a_{\alpha,i}, \mathbf{d}_{\alpha,i})$ and $\neg \phi_{\alpha,i}(\mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i})$ for some $\phi_{\alpha,i}$. By the pigeon-hole principal we may assume the $\phi_{\alpha,i}$ is always the same ϕ_{α} . (Further, since |T| is not cofinal in $\delta(T)$, we can assume the ϕ_{α} is the same ϕ for all α .)

Now the construction is completed. We expand τ to a language $\tau_{\Phi} \supset \tau$ by adding predicates P, <, R and Skolem functions. We add Skolem axioms to T to get a theory T_1 that admits quantifier elimination, requiring that these Skolem functions applied to elements of $P(P_n)$ give an element of $P(P_n)$ so that $P(P_n)$ will pick out an elementary submodel. (We make a similar requirement for $R(x, \mathbf{y})$ in the mod-case.) Let M_{α}^+ be a model of T_1 (submodel of M'_{α}) with cardinality μ_{α}^+ containing M_{α} and all the $\mathbf{d}_{\alpha,i}$ ($N_{\alpha,i}$ in the mod-case). Interpret P as the model M_{α} , P_n as M_n^{α} , and the relation < as the ordering on the triples $\langle \mathbf{e}_{\alpha,i} : i < \mu_{\alpha} \rangle$ imposed by ϕ_{α} .

Assign the Skolem functions so that the $\mathbf{e}_{\alpha,i}$ generate M'_{α} and interpret R by

$$R = \{ \widehat{e} \, \widehat{\mathbf{d}}_{\alpha,i} ; e \in M_{\alpha}, i < \mu_{\alpha}^+ \}.$$

(In the $S_{\text{mod}}(M)$ case, interpret R as $\{\widehat{e} \mathbf{d}_{\alpha,i} : i < \mu_{\alpha}^+, e \in N_{\alpha,i}\}$.)

Notation 2.11 Let Γ be the collection of types $\mathcal{P}_n \cup \mathcal{Q}_n$. Each non-principal *n*-type q over the empty set determines one element of \mathcal{P}_n and each non-principal n + m-type q determines one element of \mathcal{Q}_n :

- 1. $\mathcal{P}_n = \{ \bigwedge_{i < n} P(x_i) \} \cup \{ q(\mathbf{x}) : q \text{ is a non-principal } n \text{-type } \}$
- 2. $Q_n = \{ \bigwedge_{i < n} R(x_i, y) \} \cup \{ q(\mathbf{x}, \mathbf{y}) : q \text{ is a non-principal } n + m \text{-type, } m < \omega \}$

Now apply Morley's omitting types theorem¹ to the τ_{Φ} -theory T_1 and the collection of M_{α}^+ to get a countable sequence I of order indiscernibles and an extension Φ of T_1 , (the EM-template) such that Φ is realized in each M_{α}^+ and such that for every linear order J, $EM_{\tau}(J, \Phi) \models T_1$ and omits Γ .

Remark 2.12 (Morley's Method) The next observation requires a little care in proving Morley's theorem rather than just quoting it. The M'_{α} are generated by the $\mathbf{e}_{\alpha,i}$ and we have interpreted < so that these are exactly the domain of <. So in proving the omitting types theorem, all witnesses for the consistency of the template $\Phi(\mathbf{c})$ can be chosen from the domain of <. We use this fact below. It is this extra care that in the mind of the first author distinguishes "Morley's Method" from Morley's theorem. But this may be an idiosyncratic interpretation. The earliest mention of the phrase, I have found is in [She74] and that refers to a standard application of the two cardinal theorem for cardinals far apart.

Note that any τ_{Φ} formula $\phi(\mathbf{x})$ is in Φ if it is true of every tuple $\langle \mathbf{e}_{\alpha,i_1}, \dots \mathbf{e}_{\alpha,i_1} \rangle$ with $i_1 < i_2 < \dots i_n$. We describe a crucial such sentence.

Let $\mathbf{x}^1 \mathbf{x}^2 \mathbf{x}^3$ be a triple of sequences with the first two having the same length as $\lg(\mathbf{a}) = \lg(\mathbf{b})$ and the third has length m. Let $\psi(\mathbf{x}, \mathbf{y})$ denote:

$$\phi(\mathbf{y}^3, \mathbf{x}^1) \equiv \phi(\mathbf{y}^3, \mathbf{x}^2).$$

Let ψ_1 be the assertion that ϕ defines a linear order on its domain; this directly translates precisely Lemma 2.5.3 and is true by the displayed statement 1. These structures

¹See Appendix A.3.1 of [Bal09] for a precisely tailored version. See [She78] or [Hod93], page 587 for a version with the role of the ordering more explicit. The latter two sources make the connection with the well-ordering number clear.

clearly satisfy all the conditions of the requirements in Lemma 2.5 and we complete the proof.

 $\Box_{2.5}$ Proof of Theorem 2.1: To show instability in λ , let I be a dense linear ordering with cardinality λ and choose $J \supset I$, that realizes more than |I| cuts over I. Then $EM_{\tau}(J, \Phi)$ realizes more than λ types in $S_i^m(P(EM_{\tau}(I, \Phi)))$. To see this, consider for any cut in I realized by an element $j \in J$ the type:

$$\{\psi(\langle \boldsymbol{a}_i, \mathbf{b}_i, \mathbf{c}_i \rangle, \mathbf{x},) : i < j\} \cup \{\psi(\langle \boldsymbol{a}_i, \mathbf{b}_i, \mathbf{c}_i \rangle, \mathbf{x},) : i \ge j\}.$$

Then $\langle a_j, \mathbf{b}_j, \mathbf{c}_j \rangle$ realizes the type in $EM_{\tau}(J, \Phi)$ and $P(EM_{\tau}(J, \Phi))\mathbf{c}_j$ is an atomic set since \mathcal{Q} was omitted. For the mod-case, use the interpretation of R to define $N_{\alpha,i}$. $\Box_{2.1}$

Question 2.13 *Must an atomic class that is unstable in all* λ *have the order property?*

We say a class of atomic models has the *order property* if there is a sequence as in Lemma 2.5.3 but with the set of *all* the sequences contained in atomic set. Condition 3) only requires each triple to be atomic. In particular we don't know the various c's can appear together in any atomic model.

3 Strictly stable case

As the following examples show, it is easy to have superstable (incomplete) sentences of $L_{\omega_1,\omega}$ that are not superstable for some values below the Hanf number H. The following theorem has two easily stated corollaries. If K is not superstable then it is not stable in every λ with $\lambda^{\omega} > \lambda$. If K is superstable then it is stable in some $\lambda < H$.

The results here are related to those in [GS86] but the combinatorics here is considerably simpler than in [GS86] for two related reasons. First, we construct tree indiscernibles indexed by ${}^{<\omega}\lambda$ while they are concerned with ${}^{\leq\omega}\lambda$; the limit node is much more difficult to handle. Second, they are constructing many non-isomorphic models, we only construct many different types. To obtain these stronger results, they assume the existence of large cardinals while this paper is in ZFC.

Example 3.1 For $\alpha < \omega_1$, let ϕ_α be Morley's sentence that has a model in \beth_α but no larger model. It is easy to see that the sentences are not stable in the cardinalities where they have models. Let ψ be the Scott sentence of an infinite set with only equality. Now let ψ_α assert that either a structure has a nontrivial relation and obeys ϕ_α or just ψ . Then ϕ_α is \beth_α -unstable but stable (indeed categorical) in all cardinals beyond \beth_{ω_1} .

If one adds even joint embedding such trivial examples are no longer apparent.

Question 3.2 Is there a complete sentence of $L_{\omega_1,\omega}$ which is stable beyond H (for either mod or at) but fails stability for some cardinals less than H?

We retain the value of $\mu_{\alpha} = \beth_{\alpha}(|T|)$ from the first section but λ_{α} is redefined in the hypothesis of the next theorem.

Theorem 3.3 Suppose that for every $\alpha < \delta(T)$, there is $M^{\alpha} \in \mathbf{K}$ such that $\lambda_{\alpha} = |M^{\alpha}| \geq \mu_{\alpha}$ and $S_i^m(M^{\alpha}) > \lambda_{\alpha}$. Then for any μ with $\mu^{\aleph_0} > \mu$, \mathbf{K} is not stable in μ .

Proof. Fix for each $\alpha < \delta(T)$, $M^{\alpha} \in \mathbf{K}$ such that $|S_i^m(M^{\alpha})| > \lambda_{\alpha}$. Fix $p_{\alpha,i}$ for $i < \lambda_{\alpha}^+$, a list of distinct types in $S_i^m(M^{\alpha})$. We work throughout in a monster model \mathbb{M} of T.

To prepare for the application of an appropriate version of Morley's omitting types theorem we construct a sequence of models and certain types. For this, we construct trees of types that arise from failure of stability. The combinatorics slightly extends the classical arguments and avoids compactness. Note that this stage of the construction takes place in the original language. We will apply the following general result uniformly to each M^{α} .

Fact 3.4 Suppose $|M| \ge \mu_{\alpha+1}$ and \mathcal{P} is a collection of $> \lambda_{\alpha} = |M|$ members of $S_i^m(M)$. Then there exists a sequence $\langle \mathbf{b}_j : j < \mu_{\alpha} \rangle$ with each $\mathbf{b}_j \in M$ and a formula $\phi(\mathbf{x}, \mathbf{y}) = \phi_{\mathcal{P}}$ such that for each $j < \mu_{\alpha}$,

$$|\{p \in \mathcal{P} : i < j \to \phi(\mathbf{x}, \mathbf{b}_i) \in p \text{ but } \neg \phi(\mathbf{x}, \mathbf{b}_j) \in p\}| > \lambda_{\alpha}.$$
 (2)

Proof. We consider many possibilities for ϕ and prove one works. We choose $\{\phi_{\eta} : \eta \in T_i\}$ by induction on $i < \mu_{\alpha}$ where each T_i is a subset of ⁱ2 and each $\mathbf{b}_{\eta} \in M^{\alpha}$ so that

- 1. j < i and $\eta \in T_i$ implies $\eta \upharpoonright j \in T_j$.
- 2. if $\eta \in T_i$ then $p_{\eta} = \{\phi_{\eta \restriction j}(\mathbf{x}, \mathbf{b}_{\eta \restriction j})^{\eta(j)} : j < i\}$ is included in $> \lambda_{\alpha}$ members of \mathcal{P} .
- 3. For limit i,

 $T_i = \{ \eta \in {}^i 2 : (\forall j < i)\eta \upharpoonright j \in T_j \text{ and } p_\eta \text{ is included in } > \lambda_\alpha \text{ members of } \mathcal{P} \}$

4. if i = j + 1 then $T_i = \{\eta \hat{0}, \eta \hat{1} : \eta \in T_j\}$.

For the successor step in the induction recall the following crucial observation of Morley. Suppose there are more than |M| types over M extending a partial type p. Then there exists a formula $\phi(\mathbf{x}, \mathbf{a})$ with $\mathbf{a} \in M$ such that both $p \cup \{\phi(\mathbf{x}, \mathbf{a}) \text{ and } p \cup \{\neg \phi(\mathbf{x}, \mathbf{a})\}$ have more than |M| extensions to complete types over M. (We are extending Morley's analysis to types in $S_i^m(M)$ but the argument is just counting; there is a unique type which has more than λ_{α} extensions.)

The interesting point in the induction is the limit stage. We cannot guarantee that individual paths survive. But at each stage in the induction, we have defined types over a set of cardinality μ_{α} . So there are at most $\mu_{\alpha+1}$ types over $\{\mathbf{b}_{\eta}: \lg(\eta) < \delta\}$. So one of the paths must have more than λ_{α} extensions to $S_i^m(M)$.

So $T_{\mu_{\alpha}} \neq \emptyset$. Choose $\eta \in T_{\mu_{\alpha}}$. Let $\phi_j(\mathbf{x}, \mathbf{b}_j) = \phi_{\eta \restriction j}(\mathbf{x}, \mathbf{b}_{\eta \restriction j})^{\eta(j)}$ for $j < \mu_{\alpha}$. Since the path has length $\mu_{\alpha} = \beth_{\alpha}(T)$, by the pigeonhole principle we may assume there is a single formula ϕ . This completes the construction of the ϕ and the \mathbf{b}_j . We have the result by condition 4. Now we apply this fact to construct from the original M^{α} given in the hypothesis of Theorem 3.3 a sequence of models \hat{M}^{α} and associated sequences $\mathbf{b}_{\alpha,\rho}$ and $\mathbf{c}_{\alpha,\rho}$ for $\rho \in {}^{<\omega}\mu_{\alpha}$.

Definition 3.5 Let \hat{M}^{α} be a μ_{α}^{+} saturated elementary extension of M^{α} . We construct for each α by induction on $n < \omega$, submodels M_{n}^{α} of M^{α} and types $\{q_{\nu}^{\alpha} : \nu \in {}^{<\omega}\mu_{\alpha}\}$ with $q_{\nu}^{\alpha} \in S_{i}^{m}(M_{\lg(\nu)}^{\alpha})$ and realizations $\mathbf{c}_{\alpha,\nu} \in \hat{M}^{\alpha}$ of q_{ν}^{α} satisfying the following conditions.

- 1. $\langle M_n^{\alpha}: n < \omega \rangle$ is an increasing chain of submodels of M^{α} , each with cardinality μ_{α} .
- 2. If $k \leq n$ and $\nu \in {}^{k}\mu_{\alpha}$, then $q_{\nu}^{\alpha} \in S_{i}^{m}(M_{k}^{\alpha})$.
- 3. Each $q_{\nu}^{\alpha} \in S_i^m(M_n^{\alpha})$ has $> \lambda_{\alpha}$ extensions to $S_i^m(M^{\alpha})$
- 4. Suppose $k < r \le n$, $\nu \in {}^{k}\mu_{\alpha}$, $\rho \in {}^{r}\mu_{\alpha}$ and ρ extends ν :

$$q_{\nu}^{\alpha} \subseteq q_{\rho}^{\alpha}.$$

5. If $\nu \in {}^k \lambda_{\alpha}$, k < n, $i \neq j$, then

$$q_{\nu \widehat{i}}^{\alpha} \neq q_{\nu \widehat{i}}^{\alpha}$$

They are distinguished by the $\mathbf{b}_{\alpha,\rho}$, as specified in statement 3 below.

6. $\mathbf{c}_{\alpha,\nu} \in \hat{M}_{\alpha}$ realizes q_{ν}^{α} . (In the mod-case, $N_{\alpha,\rho}$ is the universe of an atomic model containing $M\mathbf{c}_{\alpha,\rho}$.)

Construction 3.6 We use Fact 3.4 to construct objects meeting this definition. Let the subscript x denote at or mod. By induction, for each $\rho \in {}^{n}\mu_{\alpha}$ the type $q_{\rho}^{\alpha} \in S_{x}^{m}(M_{n}^{\alpha})$ has $> \lambda_{\alpha}$ extensions to $S_{x}^{m}(M^{\alpha})$. Let $\mathcal{P}_{\rho} = \{r \in S_{x}(M_{\alpha}) : q_{\rho}^{\alpha} \subseteq r\}$ so $|\mathcal{P}_{\rho}| > \lambda_{\alpha}$. By Fact 3.4, we find $\langle \mathbf{b}_{\alpha,\rho\hat{j}} : j < \mu_{\alpha} \rangle$ and ϕ_{ρ} satisfying displayed statement 2. Let M_{n+1}^{α} be a submodel of M^{α} with $M_{n}^{\alpha} \cup \{\mathbf{b}_{\alpha,\rho} : \rho \in {}^{n+1}(\mu_{\alpha})\} \subseteq M_{n+1}^{\alpha}$ and

Let M_{n+1}^{α} be a submodel of M^{α} with $M_n^{\alpha} \cup \{\mathbf{b}_{\alpha,\rho} : \rho \in {}^{n+1}(\mu_{\alpha})\} \subseteq M_{n+1}^{\alpha}$ and with cardinality μ_{α} . $M_{n+1}^{\alpha} \subset M_{\alpha}$ so is an atomic model and each q_{ρ}^{α} extends to an atomic type over M^{α} .

For $\rho \in {}^{n}(\mu_{\alpha})$ and $i < \mu_{\alpha}$ first define

$$p_{\rho\,\widehat{i}}' = q_{\rho}^{\alpha} \cup \{\phi_{\rho}(x, \mathbf{b}_{\alpha, \rho\,\widehat{j}}) : j < i\} \cup \{\neg \phi_{\rho}(x, \mathbf{b}_{\alpha, \rho\,\widehat{i}})\}.$$

Since $\lambda_{\alpha} < |\{r \in S_x(M^{\alpha}) : p'_{\rho} \subseteq r\}|$, we can find $p^{\alpha}_{\widehat{\rho}i} \in S^m_x(M^{\alpha}_n)$ extending $p'_{\widehat{\rho}i}$ such that $\mathcal{P}_{\widehat{\rho}i} = \{r \in S_x(M^{\alpha}) : p_{\widehat{\rho}i} \subseteq r\}$ has cardinality $> \lambda_{\alpha}$. Note that

$$p_{\widehat{\rho}\widehat{i}}^{\alpha} \supseteq q_{\rho}^{\alpha} \cup \{\phi_{\rho}(x, \mathbf{b}_{\alpha, \widehat{\rho}\widehat{j}}) : j < i\} \cup \{\neg \phi_{\rho}(x, \mathbf{b}_{\alpha, \widehat{\rho}\widehat{i}})\}.$$

This completes the n + 1st stage of the construction. So we can construct the M_n^{α} and $\{q_{\nu,i} : \nu \in {}^{<\omega}\mu_{\alpha}\}\rangle$, \hat{M}^{α} and by μ_{α}^+ -saturation choose $\mathbf{c}_{\alpha,\rho} \in \hat{M}^{\alpha}$. In the mod-case choose an atomic model $N_{\alpha,\rho}$ with $M^{\alpha}\mathbf{c}_{\alpha,\rho} \subset N_{\alpha,\rho} \prec \hat{M}^{\alpha}$. Note

$$\{\phi_{\rho}(\mathbf{c}_{\alpha,\widehat{\rho}i},\mathbf{b}_{\alpha,\widehat{\rho}j}): j < i\} \cup \{\neg\phi_{\rho}(\mathbf{c}_{\alpha,\widehat{\rho}i},\mathbf{b}_{\alpha,\widehat{\rho}i})\}.$$
(3)

With the construction complete, we expand τ to a language $\tau_{\Phi} \supset \tau$ in two stages. Form τ' by adding predicates $P, P_n, <, <^*, R$ and Skolem functions. We add Skolem axioms to T to get a theory T' that admits quantifier elimination, requiring that these Skolem functions applied to elements of P give an element of P so that P will pick out an elementary submodel.

Let M_{α}^{+} be a model of T (submodel of \hat{M}^{α}) with cardinality μ_{α} containing M_{α}^{α} for $n < \omega$ and all the $\mathbf{c}_{\alpha,\rho}$ Assign the τ' -Skolem functions so that $P(\hat{M}^{\alpha}) = M^{\alpha} = \bigcup_{n < \omega} M_{n}^{\alpha}$ is generated by the $\mathbf{b}_{\alpha,\rho}$ for $\rho \in {}^{<\omega}\mu_{\alpha}$. Let X_{α} be the tree with domain $\langle \mathbf{b}_{\alpha,\rho} : \rho \in {}^{<\omega}(\mu_{\alpha}) \rangle$ and the following relations. Interpret < as the partial order on the $\langle \mathbf{b}_{\alpha,\rho} : \rho \in {}^{<\omega}(\mu_{\alpha}) \rangle$ given by inclusion on the ρ -indices. Let $<^{*}$ be a linear order of the $\langle \mathbf{b}_{\alpha,\rho} : \rho \in {}^{<\omega}(\mu_{\alpha}) \rangle$ given by lexicocographic order on the ρ -indices. Interpret R as

$$\{\widehat{e} \, \widehat{\mathbf{c}}_{\alpha,\rho} : \rho \in {}^{< n}(\mu_{\alpha}), e \in \bigcup_{n < \omega} M_n^{\alpha} \}.$$

Form τ_{Φ} by adding function symbols F_n . Define $F_n(\mathbf{b}_{\alpha,\rho}) = \mathbf{c}_{\alpha,\rho}$. Now let T_1 be the collection of all $L(\tau_{\Phi})$ -sentences that are true in each \hat{M}_{α} .

In the $S_{\text{mod}}(M)$ case, we must do a bit more. Interpret R as

$$\{\widehat{\mathbf{e}} \, \widehat{\mathbf{c}}_{\alpha,\rho} : \rho \in {}^{< n}(\mu_{\alpha}), \text{ and } \mathbf{e} \in N_{\alpha,\rho}\}$$

Define the τ' -Skolem functions so that the Skolem closure of $M\mathbf{c}_{\alpha,\rho}$ is $N_{\alpha,\rho}$. This implies that if $R(\mathbf{e}, \mathbf{c}_{\alpha,\rho})$ holds then \mathbf{e} is a sequence given by τ' -Skolem functions with arguments a finite number of members of $P(M_{\alpha}^+)$ and $\mathbf{c}_{\alpha,\rho}$.

By conditions 4-6 of Definition 3.5,

Claim 3.7 For any finite linearly ordered initial <-segment of the tree with length n + 1, enumerated by $\mathbf{x}_0, \ldots \mathbf{x}_n$, (so $P_i(\mathbf{x}_i)$):

1. $\bigwedge_{i \leq n} [P_i(\mathbf{z}) \land \mathbf{z} <^* \mathbf{x}_i \to \phi_i(F_n(x_n), \mathbf{z})]$ 2. $\bigwedge_{i \leq n} \neg \phi_i(F_n(x_n), \mathbf{x}_i).$

The universal quantification of each such sentence is true in each \hat{M}_{α} and so is in T_1 .

As in Notation 2.11 let Γ be the collection of types:

- 1. $\mathcal{P}_n = \{ \bigwedge_{i < n} P(x_i) \} \cup \{ q(\mathbf{x}) : q \text{ is a non-principal } n \text{-type } \}$
- 2. $Q_n = \{ \bigwedge_{i < n} R(x_i, \mathbf{y}) \} \cup \{ q(\mathbf{x}, \mathbf{y}) : q \text{ is a non-principal } n + m \text{-type, } m < \omega \}$

Now apply the omitting types theorem (as stated in Section 4) to the τ_{Φ} -theory T_1 and the collection of M_{α}^+ to get a countable set of tree-indiscernibles in order type ${}^{<\omega}\omega$ and an extension Φ of T_1 , (the EM-template) such that for every tree of J of order ${}^{<\omega}\lambda$, $EM_{\tau}(J, \Phi) \models T_1$ and omits Γ .

Finally we must show there are many types; we separate the mod and at cases.

Claim 3.8 If $\lambda^{\omega} > \lambda$ then there is an I with $|I| = \lambda$ such that $S^m_{at}(M_I) > \lambda$, where $M_I = EM(I, \Phi) \upharpoonright P$.

Proof. Note that by displayed statement 3 and Claim 3.7 we have:

- 1. If $\rho, \widehat{\rho}i \in I$, $\operatorname{tp}(F_n(\rho)/P_n(M)) \subseteq \operatorname{tp}(F_{n+1}(\widehat{\rho}i)/P_{n+1}(M))$.
- 2. If $\rho \in I$ and $i \neq j$,

$$\operatorname{tp}(F_{n+1}(\hat{\rho_j})/P_{n+1}(M)) \neq \operatorname{tp}(F_{n+1}(\hat{\rho_i})/P_{n+1}(M)).$$

Now in any $M_I = EM(I, \Phi)$ for any $\rho \in J$ define $p_\rho \in S^m_{\mathrm{at}}(P_N(M_I) = \operatorname{tp}(F_n(\rho), P_n(M))$. Now letting $p_\eta \in S^m_{\mathrm{at}}(P(M_I))$ be $\bigcup_{i < \omega} p_{\eta \upharpoonright n}$, we find λ^{ω} members of $S^m_{\mathrm{at}}(P(M_I))$. The definition of S^m_{at} guarantees the union is in S^m_{at} . $\Box_{3.8}$

Now we extend this result to mod.

Claim 3.9 If $\lambda^{\omega} > \lambda$ then there is an I with $|I| = \lambda$ such that $S_{\text{mod}}^m(M_I) > \lambda$, where $M_I = EM(I, \Phi) \upharpoonright P$.

Proof. We need to construct an atomic model N_{η} containing $M_I \mathbf{c}_{\eta}$ (from the proof of Claim 3.8). The natural choice is the τ' -Skolem closure of $M_I \mathbf{c}_{\eta}$. The reason the reduct of this structure to τ is atomic is that any finite sequence is of the form a, **b** where the a come from $P_n(M_I)$ (for a fixed n) and each of the **b** has the form $G(a, \mathbf{c}_{\eta})$ where G is a τ' -Skolem function. But then the τ type of $a\mathbf{b}$ is the same as the τ -type of a sequence $a'\mathbf{b}'$ where $a' \in P_n(\hat{M}^{\alpha})$ and each $b' \in N_{\alpha,\rho}$ is of the form $G(a', \mathbf{c}_{\eta \upharpoonright n})$. $\Box_{3.9}$

Remark 3.10 We investigate the difference in hypotheses between Theorem 2.1 and Theorem 3.3^2 . We first study Theorem 2.1.

Let $\kappa = |M_{\alpha}|$.

Case 1. $\kappa \leq \beth_{\alpha}$: then $\kappa^{\beth_{\alpha}}$ is equal to $\beth_{\alpha}^{\beth_{\alpha}} = 2^{\beth_{\alpha}} = \beth_{\alpha+1}$. The assumption of the theorem is that $|S_i^m(M_{\alpha})| > \kappa^{\beth_{\alpha}} = 2^{\beth_{\alpha}}$. This case is not possible since $|S_i^m(M_{\alpha})| \leq 2^{\kappa} \leq 2^{\beth_{\alpha}}$.

Case 2. $\kappa > \beth_{\alpha}$. On one hand we have $\kappa \leq \kappa^{\beth_{\alpha}}$; on the other $\beth_{\alpha+1} = \beth_{\alpha}^{\beth_{\alpha}} \leq \kappa^{\beth_{\alpha}}$. Thus, $\kappa^{\beth_{\alpha}} \geq \max(\beth_{\alpha+1}, \kappa)$. The hypothesis in the theorem says that $|S_i^m(M_{\alpha})| > \kappa^{\beth_{\alpha}}$, so $|S_i^m(M_{\alpha})| > \max(\beth_{\alpha+1}, \kappa)$.

This leads to two cases:

Case 2a. $\kappa \geq \beth_{\alpha+1}$: then $|S_i^m(M_\alpha)| > \max(\beth_{\alpha+1}, \kappa^{\beth_\alpha}) \geq \kappa$. So the requirement is at least instability in κ .

Case 2b. $\exists_{\alpha} < \kappa < \exists_{\alpha+1}$: then $|S_i^m(M_{\alpha})| > \max(\exists_{\alpha+1}, \kappa^{\exists_{\alpha}}) = \exists_{\alpha+1} > \kappa$. This yields instability in κ . (Under GCH, of course, this case is empty.)

In general, the hypothesis in case 2a) requires more than instability in κ : if κ has cofinality less than or equal to the cofinality of \beth_{α} , then $\kappa^{\beth_{\alpha}} > \kappa$, and the number of types needs to be (possibly) much greater than κ .

²This analysis was worked out by the first author and Alexei Kolesnikov.

Theorem 3.3 asserts that K is unstable in some cardinal then it is unstable in any λ with $\lambda^{\omega} > \lambda$ so it is analogous to the first order case. Further it asserts that the first stability cardinal for a superstable class is less than H.

Thus, in Theorem 2.1 we assume 'serious' instability and get instability everywhere and in Theorem 3.3 we assume "just" instability, and get instability for cardinals of countable cofinality only.

We further analyze case 2a under GCH. The possible values of $\kappa^{\Box_{\alpha}}$, given that $\kappa > \Box_{\alpha+1}$, become κ and $2^{\kappa} = \kappa^+$ (the first is the case when the cofinality of κ is greater than the cofinality of \Box_{α} ; otherwise, the second alternative holds).

Under the GCH the difference between 'serious' and 'just' instability disappears. Moreover, we can expect to find M_{α} satisfying the hypothesis only for $|M_{\alpha}|$ of cofinality greater than the cofinality of \beth_{α} . So under the GCH, the difference between the hypotheses in 2.1 and 3.2 disappears, but the conclusion of 3.2 is weaker.

4 Tree Indiscernibility

The main result of this section is the existence of tree indiscernibles as needed in the previous section. But we take the occasion to discuss the role of various types of index sets for indiscernible collections and to make explicit the role of expanding the vocabulary when finding indiscernibles in various contexts.

The theorem reported here is implicit in the literature (e.g. [She78, GS86]) but we could not find an explicit statement. Theorem VII.3.6 of [She78] finds an indiscernible tree in the first order case on $\leq \omega \omega$ but we want to omit types as well. The basic plan of the proof dates to Morley [Mor65]. We indicate the modifications needed for the more complicated combinatorics to build models to omit types that are over indiscernible trees instead of over linear orders.

Many variants of tree indiscernibles are used in various parts of model theory; we sketch the contexts to point out where the current version lies.

| | linear order | $<\omega 2$ | $ ^{<\omega}\lambda$ | $\leq \omega \lambda$ |
|--------------------|--------------|-------------|----------------------|-----------------------|
| $<\in \tau$ | 1 | 2 | 3 | 4 |
| $<\in \tau_{\Phi}$ | 5 | 6 | 7 | 8 |

In this chart the left most column labels the row and there are four numbered columns. In the first row, the ordering is explicitly defined in the base language; in the second row it is not. Thus the first row describes examples where the (tree)-ordering is definable in the original vocabulary.

Indiscernibles may be ordered by linear orders, or trees of the form ${}^{<\omega}2$, ${}^{<\omega}\lambda$ or even ${}^{\leq\omega}2$, ${}^{\leq\omega}\lambda$. We may want to find the ordering in the basic language (to witness unstability at some level) or not (to avoid introducing instability). In some cases the order is explicit in the expanded language; in others it is not. Ehrenfeucht and Mostowski (5) did not introduce the order to the base language (so second row) and built the tree over a linear order (first column). Morley's proof that \aleph_1 -categoricity implies ω -stability occupies the same place in the chart. He is counting the number of τ types and there is certainly no ordering in the vocabulary τ . In his construction of many models of unstable theories [She71, She78], Shelah (1) is in the first column, first row. To investigate the difference in stability spectrum for stable but not superstable theories, we want (3) the first row, third column. But to count the number of models of superstable theory involves (4) trees of height $\omega + 1$. The proof here differs from [She78], where the number of models of an unsuperstable theory is computed, because in working with $L_{\omega_1,\omega}$, we must omit types. In VII.3.6 of [She78], Erdos-Rado is applied to show the existence of a 'uniform' β -tree implies the existence of a tree of indiscernibles indexed by $^{<\omega}\omega$. The use (2) of trees indexed by $2^{\leq\omega}$ to construct many models in \aleph_1 if a countable theory is not ω -stable appears in [She78]. (The tree is found in VI.3.7; it is used to construct many models in VIII.1.2.) An exposition of this result and some extensions to uncountable languages occur in [Bal89]. There are further applications to two-cardinal models [She75, She76] and to Peano arithmetic (6) [MP84]. Tree indiscernibles on ${}^{<\omega}2$ rely on Halpern-Lauchli; tree indiscernibles on ${}^{<\omega}\omega$ rely on Erdos-Rado. The construction of many models from infinitary order properties in [GS86] (4) requires large cardinal axioms for the combinatorics.

We see three steps in this kind of construction. The references in parentheses are to the application of this method to the proof of the strictly stable case in this paper.

- 1. Model theoretic construction of specific syntactic-combinatoric configurations on models. (Construction 3.6.)
- 2. Application of Erdos-Rado or Halpern-Lauchli and compactness to extract a countable family of indiscernibles. (Theorem 4.7.)
- 3. Application of Ehrenfeucht-Mostowski models to obtain models of arbitrary cardinality. (Claim 3.8.) This is sometimes called 'stretching'.

We first establish some background notation. The exact vocabulary for describing the partial order is significant; ours is considerably more expressive than that in [She75].

Notation 4.1 1. A tree T is a subset of $\leq \omega \lambda$ that is closed under initial segment.

- 2. atp means atomic (quantifier-free) type.
- 3. The vocabulary τ^* will denote the vocabulary for trees we use. It contains the partial order on the tree, <, the lexiocographic order on the tree <*, and the levels P_n . τ_n^* omits the P_i with i > n.
- 4. When elements a_{η} and a_{τ} in a structure M are indexed by $\eta, \tau \in T$ that realize the same quantifier free τ^* -type in the tree then a_{τ} and a_{η} have the same length.
- 5. If ν is an *n*-element sequence from T, a_{ν} denotes $\langle a_{\nu(0)}, \ldots a_{\nu(n-1)} \rangle$.

Definition 4.2 For any vocabulary τ , let M be a τ -structure and Σ a set of τ -formulas. If $\operatorname{atp}_{\tau^*}(\eta/\emptyset) = \operatorname{atp}_{\tau^*}(\nu/\emptyset)$ implies $\operatorname{tp}_{\Sigma}(\boldsymbol{a}_{\eta}/\emptyset) = \operatorname{tp}_{\Sigma}(\boldsymbol{a}_{\nu}/\emptyset)$ in M then we call $\langle \boldsymbol{a}_{\eta} : \eta \in \boldsymbol{T} \rangle \subset M$ a set of Σ -tree indiscernibles:

We just say tree indiscernibles if Σ contains all formulas in $L(\tau)$.

We rely on a combinatorial lemma that follows from Erdos-Rado. The result is proved as Theorem 2.6 in the appendix to [She78]. A stronger result (the bound on k(m,n) is smaller) with a shorter proof appears in the appendix of [GS86].

Lemma 4.3 ([She78]) For every $n, m < \omega$, there is a $k = k(n, m) < \omega$ such that if $\lambda = \beth_k(\chi)^+$ the following is true. For any function $f : [\le^n \lambda]^m \to \chi$, there exists a $T \subseteq \le^n \lambda$ such that

- 1. Each $\eta \in T$ has χ^+ immediate successors in T.
- 2. If ν and τ are *m*-tuples from **T** with $\operatorname{atp}_{\tau^*}(\eta/\emptyset) = \operatorname{atp}_{\tau^*}(\nu/\emptyset)$, then

 $f(\tau) = f(\eta).$

We now prove the theorem on the existence of tree-indiscernibles. In order to be clear about the definability of the tree in the original vocabulary we extend Notation 4.1 and are quite pedantic about the vocabularies involved.

- **Notation 4.4** 1. τ_{Φ} includes both τ and τ^* and includes Skolem functions for τ_{Φ} , where the Skolem axioms and relations with crucial τ -formulas are axiomatized in a τ_{Φ} -theory T_1 .
 - 2. The set of constants C which guarantee the consistency of the order are added to τ_{Φ} .
 - 3. Σ_i denotes the set of $\phi \in \tau_{\Phi} \{P_i : j > i\}$ with at most *i* free variables.

Tree-indiscernibles are a special case of generalized indiscernibility as defined in VII.2 of [She78]. Indiscernibles indexed by other types of structure appear for example in [LS03, DŎ4, Sco]. The following notion of *modeling property*, based on one introduced by Scow[Sco] in a slightly different context is helpful for stating the results here. The point is that although the type of an infinite collection of indiscernibles may not be realized in any of the input models, each type of a finite subsequence is. Thus properties of finite character (such as realizing a finite type) follow immediately if the indiscernibles have the modeling property. We use \approx for isomorphic.

Definition 4.5 A collection of Σ -tree-indiscernibles $B = \{b_{\eta} : \eta \in T\}$ has the modeling property if it is derived from a sequence (M_{α}, X_{α}) (where $M_{\alpha} \supset X_{\alpha} = \{a_{\eta} : \eta \in T_{\alpha}\}$, and $T_{\alpha} \approx T$ for $\alpha < H$) such that for every finite sequence ν from T and every sequence \mathbf{b}_{ν} from B and some α there is a sequence $\mathbf{a}_{\nu'} \in X_{\alpha}$ with ν' having the same τ^* -type as ν and such that $\mathbf{a}_{\nu'}$ and \mathbf{b}_{ν} have the same Σ -type.

Note that in the argument below when the X_{α} are refined using Lemma 4.3 a tuple $a_{\nu} \in X^{i}_{\alpha,n}$ was originally named $a_{\nu'} \in X^{0}_{\alpha+m^*,n}$ (where $m^* < \omega$ can be easily computed). But, ν and ν' realize the same τ^* -type.

Remark 4.6 There are at least four approaches to the proof of Morley's omitting types theorem that differ subtly. In [CK73, Mar02]³ the language is countable and there are

³Compare comments on the proof in [CK73]. The stated result is the existence of large models omitting types without mentioning indiscernibility.

separate steps to guarantee indiscernibility and omission of the types (meeting indiscernibility type omission requirements in turn for each formula and for each type). In the argument here, we use the Skolemization of the models M_{α} to deduce the omission of types from the indiscernibility. This argument strategy is forced because in dealing with uncountable languages, working with one formula at each step makes the induction too long. We replace this by working with all formulas with *n* free variables at step *n*. The arguments in [She78, GL02, GS86] employ nonstandard-models of set theory. Finally, the arguments in [Hod87, Kei71], work directly in infinitary logic using Hintikka sets or consistency properties. The arguments of [She78, GS86, Hod87] make the connection with well-ordering numbers explicit. Tsuboi [Tsu08] shows that a family of $< 2^{\aleph_0}$ complete types that is omitted up to \aleph_{ω_1} can be omitted in arbitrarily large models; this argument introduces some new combinatorial ideas.

Recall that $\mu_{\alpha} = \beth_{\alpha}(|T|)$. Writing μ_{α} rather than \beth_{α} and considering M_{α} for $\alpha < \delta(T) = (2^{|T|})^+$ is part of the price for dealing with uncountable T.

Note that when applying this theorem in Section 3, the M_{α} here are the M_{α}^+ (as Skolemized) there.

Theorem 4.7 Let T_1 be a theory with Skolem functions in a vocabulary τ_{Φ} . Suppose for $\alpha < \delta(T)$, there exists a model M_{α} of T_1 with $|M_{\alpha}| \ge \mu_{\alpha}$ such that M_{α} omits a family Γ of τ -types. τ_{Φ} contains the vocabulary τ^* and X_{α} is a set of elements in M_{α} that form a tree of type ${}^{<\omega}\mu_{\alpha}$ in M_{α} defined by the interpretations of $<, <^*, P_n$. In particular $X_{\alpha,n}$ is the restriction of X_{α} to P_n ; it has order type ${}^{\leq n}\mu_{\alpha}$.

Then, there is a countable set of tree-indiscernibles $C = \langle \mathbf{c}_{\tau} : \tau \in I \rangle$ with I of order type $\langle \omega \omega \rangle$ such that C has the modeling property with respect to (M_{α}, X_{α}) and an extension Φ of T such that for every tree J of the form $\langle \omega \rangle$, $EM_{\tau}(J, \Phi) \models T$, witnesses the universal τ_{Φ} -sentences that are true on all X_{α} , and omits Γ .

Proof. After expanding the language τ_{Φ} with new constants $\langle c_{\rho} : \rho \in \langle \omega \omega \rangle$, we need to demonstrate the consistency of the following families of sentences.

- 1. $c_{\rho} \neq c_{\eta}$ if $\rho \neq \eta$.
- 2. For each τ_{Φ} -formula $\phi(\mathbf{v})$, for each quantifier-free τ^* -type r. If η, ν both realize r,

$$\phi(\mathbf{c}_{\nu}) \equiv \phi(\mathbf{c}_{\eta}).$$

3. For each ℓ -type $p \in \Gamma$, for each sequence of $\ell \tau_{\Phi}$ -terms $t_i(\mathbf{u})$ with $\lg(\mathbf{u}) = m$ $(\mathbf{t}(\mathbf{u}) = \langle t_0(\mathbf{u}), \dots, t_{\ell-1}(\mathbf{u}) \rangle)$ and each quantifier-free τ^* -m-type r, there is a $\phi_p(v_0, \dots, v_{\ell-1})$, such that if ν realizes r

$$\neg \phi_p(\mathbf{t}(\mathbf{c}_{\nu}))$$

If ψ is the universal quantification of a τ_Φ-formula χ(x₁,...x_n) that is true in all X_α (i.e on the substructure of the τ_Φ expansion of M_α with universe X_α) then χ(c₁,...c_n) ∈ Φ.

Let $T \subseteq {}^{<\omega}\lambda$ and $T_n = T \cap {}^{\leq n}\lambda$. We begin with pairs $(M_{\alpha}, X^0_{\alpha,n})$ for $n < \omega$, a model M_{α} , and a subset $X^0_{\alpha,n} = \{a_{\tau} : \tau \in T_{\alpha,n}\}$ which contains a sufficiently large tree as in the hypothesis of the theorem. Here, $T_{\alpha} \subseteq {}^{<\omega}\mu_{\alpha}$ and $T_{\alpha,n} = T \cap {}^{\leq n}\mu_{\alpha}$.

We construct by induction for $i < \omega$ and for each n a pair $(M^i_{\alpha}, X^i_{\alpha,n})$ with $X^i_{\alpha,n} = \{a_{\tau} : \tau \in \mathbf{T}^i_{\alpha,n}\} \subset \bigcup_{j \leq n} P_j(M^i_{\alpha})$ with $(\mathbf{T}^i_{\alpha,n}, <, <^*) \approx \leq^n \mu_{\alpha}$. And we construct the diagram Φ , checking its finite consistency. Let Φ_0 include all τ_{Φ} sentences true in all $X^0_{\alpha,n}$ and the assertion that the c_{ρ} are distinct.

At stage *i*, we apply the next result, Claim 4.8.

Claim 4.8 Let S_n be the collection of τ_{Φ} -n-types over the empty set which are realized in $\bigcup_{i \leq n} P_n(M_{\alpha})$ (i.e. the Σ_n -types). The sequence $(M^i_{\alpha}, X^i_{\alpha,n})$ has the property that for each α :

If $\eta, \nu \in T^i_{\alpha,n}$ both realize the same quantifier-free τ^* -type r, and $n \leq i$ then for each $\phi \in \Sigma_n$

$$\phi(\mathbf{c}_{\eta}) \equiv \phi(\mathbf{c}_{\nu}). \tag{4}$$

Moreover, $(X^i_{\alpha,n}, <, <^*) \approx {}^{\leq n} \mu_{\alpha}$.

Proof. Consider $(M_{\alpha+k}^i, X_{\alpha+k,i}^i)$ where k = k(m, i). Let $f : [X_{\alpha+k,i}^i]^m \to S_n$, where $f(\nu) = s$ if $\operatorname{tp}_{\tau_{\Phi}}(a_{\nu}) = s$. Now by Lemma 4.3, there is a $Y_{\alpha,i}$ (contained in $X_{\alpha+k,i}^i \subset \bigcup_{j \leq i} P_j(M_{\alpha})$) and with $(Y_{\alpha,i}, <, <^*) \approx {}^{\leq n}\mu_{\alpha}$ and (4) is true on $Y_{\alpha,i}$. Denote $Y_{\alpha,i}$ as $X_{\alpha,i}^{i+1}$ and $M_{\alpha+k}^i$ as M_{α}^{i+1} . For $j \geq i$, let $X_{\alpha,j}^{i+1}$ be the elements of $X_{\alpha+k,j}^i$ that extend members of $Y_{\alpha,i} = X_{\alpha,i}^{i+1}$.

We also refine (and rename for convenience) the index set of ordinals to guarantee that for all α , each τ^* -type in S_n is given the same truth value for all tuples from $X_{\alpha,i}^i$ realizing r. This assignment gives us Φ_{n+1} . We can do this because at any stage, the number of Σ_n -theories is at most $2^{|T|}$ which is not cofinal in $(2^{|T|})^+$. Note that as i increases in this induction, the indiscernibility is being insured for larger Σ_i . Since the Σ_i are increasing this results in a consistent theory Φ giving tree-indiscernibility in $L(\tau_{\Phi})$.

At stage *i*, we have assigned to each τ_i^* type *r*, a complete Σ_i -diagram in τ_{Φ} ; each formula $\phi(\mathbf{v}) \in \Sigma_i$ has a fixed truth value for all \mathbf{c}_{η} where η realizes *r*. In particular, since all M_{α} omit each ℓ -type $p \in \Gamma$ for any finite ℓ , for each sequence of ℓ -Skolem functions **t** in a most *m*-variable, and each η realizing a τ^* -type in *m*-variables there is a $\phi_p \in \Sigma_{\ell \cdot m}$ with $\phi_p \in p$ and $\neg \phi_p(\mathbf{t}(\mathbf{c}_{\eta})$.

 $\Box_{4.7}$

This completes the general proof for obtaining tree indiscernibles and so the proof of Theorem 3.3 is complete as well.
