# The complete (real) hyperbolic structure

$M = S^3 \setminus K$  carries a complete hyperbolic metric

$M$  can be realized as a quotient

$$\Gamma \setminus H_{\mathbb{R}}^3$$

where  $\Gamma \subset PSL_2(\mathbb{C})$  is a lattice (discrete group with quotient of finite volume)

- ▶ One cusp with cross-section a torus.
- ▶ Discovered by R. Riley (1974)
- ▶ Part of a much more general statement about knot complements/3-manifolds (Thurston)

# Holonomy representation

For example by Wirtinger, get

$$\pi_1(M) = \langle g_1, g_2, g_3 \mid g_1 g_2 = g_2 g_3, g_2 = [g_3, g_1^{-1}] \rangle,$$

with fundamental group of the boundary torus generated by

$$g_1 \text{ and } [g_3^{-1}, g_1][g_1^{-1}, g_3]$$

Alternatively

$$\pi_1(M) = \langle a, b, t \mid tat^{-1} = aba, tbt^{-1} = ab \rangle.$$

The figure eight knot complement fibers over the circle, with punctured torus fiber.

## Holonomy representation (cont.)

Search for  $\rho : \pi_1(M) \rightarrow PSL_2(\mathbb{C})$  with  $\rho(g_1) = G_1$ ,  
 $\rho(g_3) = G_3$ ,

$$G_1 = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad G_3 = \begin{pmatrix} 1 & 0 \\ -a & 1 \end{pmatrix}$$

Requiring

$$G_1[G_3, G_1^{-1}] = [G_3, G_1^{-1}]G_3$$

get  $a^2 + a + 1 = 0$ , so

$$a = \frac{-1 \pm i\sqrt{3}}{2} = \omega \text{ or } \bar{\omega}.$$

## Triangulation picture

Can also get the hyperbolic structure gluing two **ideal tetrahedra**, with invariants  $z, w$ .

Compatibility equations:

$$z(z - 1)w(w - 1) = 1$$

For a **complete** structure, ask the boundary holonomy to have derivative 1, and this gives

$$z = w = \omega$$

# Complete spherical CR structures

Spherical CR structure arising as the **boundary of a ball quotient**.

Ball quotient:  $\Gamma \backslash \mathbb{B}^2$ , where  $\Gamma$  is a discrete subgroup of  $\text{Bihol}(\mathbb{B}^2) = \text{PU}(2, 1)$ .

The manifold at infinity inherits a natural spherical CR structure, called “complete” or “uniformizable”.

## Domain of discontinuity

$\Gamma \subset PU(2, 1)$  discrete

- ▶ Domain of discontinuity  $\Omega_\Gamma$
- ▶ Limit set  $\Lambda_\Gamma = S^3 - \Omega_\Gamma$

The orbifold/manifold at infinity of  $\Gamma$  is  $\Gamma \backslash \Omega_\Gamma$

- ▶ Manifold only if no fixed points in  $\Omega_\Gamma$  (isolated fixed points inside  $\mathbb{B}^2$  are OK);
- ▶ Can be empty (e.g. when  $\Gamma$  is (non-elementary) and a normal subgroup in a lattice).

## Biholomorphisms of $\mathbb{B}^2$

Up to scaling,  $\mathbb{B}^2$  carries a unique metric invariant under the  $PU(2, 1)$ -action, the Bergman metric.

$$\mathbb{B}^2 \subset \mathbb{C}^2 \subset P_{\mathbb{C}}^2$$

With this metric: **complex hyperbolic plane**.

- ▶ Biholomorphisms of  $\mathbb{B}^2$ : restrictions of projective transformations (i.e. linear tsf of  $\mathbb{C}^3$ ).
- ▶  $A \in GL_3(\mathbb{C})$  preserves  $\mathbb{B}^2$  if and only if

$$A^* H A = H$$

where

$$H = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Equivalent Hermitian form:

$$J = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}$$

Siegel half space:

$$2\Im(w_1) + |w_2|^2 < 0$$

Boundary at infinity  $\partial_\infty H^2\mathbb{C}$  (minus a point) should be viewed as the **Heisenberg group**,  $\mathbb{C} \times \mathbb{R}$  with group law

$$(z, t) * (w, s) = (z + w, t + s + 2\Im(z\bar{w})).$$

- ▶ Copies of  $H_{\mathbb{C}}^1$  (affine planes in  $\mathbb{C}^2$ ) have curvature  $-1$
- ▶ Copies of  $H_{\mathbb{R}}^2$  ( $\mathbb{R}^2 \subset \mathbb{C}^2$ ) have curvature  $-1/4$  (linear only when through the origin)
- ▶ No totally geodesic embedding of  $H_{\mathbb{R}}^3$ !

For this normalization, we have

$$\cosh \frac{1}{2} d(z, w) = \frac{|\langle Z, W \rangle|}{\sqrt{\langle Z, Z \rangle \langle W, W \rangle}}$$

where

- ▶  $Z$  are homogeneous coordinates for  $z$
- ▶  $W$  are homogeneous coordinates for  $w$

# Isometries of $H_{\mathbb{C}}^2$

## Classification of (non-trivial) isometries

- ▶ **Elliptic** ( $\exists$  fixed point inside)
  - ▶ regular elliptic (three distinct eigenvalues)
  - ▶ complex reflections
    - ▶ in lines
    - ▶ in points
- ▶ **Parabolic** (precisely one fixed point in  $\partial H_{\mathbb{C}}^2$ )
  - ▶ Unipotent (some representative has 1 as its only eigenvalue)
  - ▶ Screw parabolic
- ▶ **Loxodromic** (precisely two fixed points in  $\partial H_{\mathbb{C}}^2$ )

$PU(2, 1)$  has index 2 in  $\text{Isom}H_{\mathbb{C}}^2$  (complex conjugation).

## Central question

### Which 3-manifolds admit a complete spherical CR structure?

In other words:

Which 3-manifolds occur as the manifold at infinity  $\Gamma \backslash \Omega_\Gamma$  of some discrete subgroup  $\Gamma \subset PU(2, 1)$ ?

Silly example: lens spaces! Take  $\Gamma$  generated by

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{2\pi i/q} & 0 \\ 0 & 0 & e^{2\pi ip/q} \end{pmatrix}$$

with  $p, q$  relatively prime integers (in this case  $\Omega_\Gamma = S^3$ ).

## CR surgery (Schwartz 2007)

$M$  a complete spherical CR structure on an open manifold with torus boundary.

If we have

1. The holonomy representation deforms
2.  $\Gamma \setminus \Omega$  is the union of a compact region and a “horotube”
3. Limit set is porous

Then  $\infty$  many Dehn fillings  $M_{p/q}$  admit a complete spherical CR structures.

Not effective, which  $p/q$  work?

## Preliminary analysis

Falbel 2008:

- ▶  $Im(\rho_1) \triangleleft PU(2, 1, \mathbb{Z}[\omega])$
- ▶  $Im(\rho_2) \subset PU(2, 1, \mathbb{Z}[\sqrt{-7}])$

In particular,  $\rho_1$  and  $\rho_2$  are discrete.

$Im(\rho_1)$  has empty domain of discontinuity (same limit set as the lattice  $PU(2, 1, \mathbb{Z}[\omega])$ ).

Action of  $Out(\pi_1(M)) \rightsquigarrow$  up to conjugation,

$$\rho_3 = \rho_2 \circ \tau$$

for some outer automorphism  $\tau$  of  $\pi_1(M)$  (orientation reversing homeo of  $M$ ).

## Preliminary analysis

Falbel 2008:

- ▶  $\text{Im}(\rho_1) \triangleleft PU(2, 1, \mathbb{Z}[\omega])$
- ▶  $\text{Im}(\rho_2) \subset PU(2, 1, \mathbb{Z}[\sqrt{-7}])$

In particular,  $\rho_1$  and  $\rho_2$  are discrete.

$\text{Im}(\rho_1)$  has empty domain of discontinuity (same limit set as the lattice  $PU(2, 1, \mathbb{Z}[\omega])$ ).

Action of  $\text{Out}(\pi_1(M)) \rightsquigarrow$  up to conjugation,

$$\rho_3 = \rho_2 \circ \tau$$

for some outer automorphism  $\tau$  of  $\pi_1(M)$  (orientation reversing homeo of  $M$ ).

## Complete structure for $4_1$ .

Write

- ▶  $\Gamma = \text{Im}(\rho_2)$ ,
- ▶  $G_k = \rho_2(g_k)$ .

$$G_1 = \begin{pmatrix} 1 & 1 & -\frac{1+\sqrt{(7)}i}{2} \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix} \quad G_2 = \begin{pmatrix} 2 & \frac{3-i\sqrt{7}}{2} & -1 \\ -\frac{3+i\sqrt{7}}{2} & -1 & 0 \\ -1 & 0 & 0 \end{pmatrix}$$

$$G_3 = G_2^{-1} G_1 G_2.$$

- ▶  $G_1, G_3$  unipotent
- ▶  $G_2$  regular elliptic of order 4.

## Back to Dirichlet domains

To see that  $\rho_2$  does the job, one way is to study **Dirichlet/Ford domains** for  $\Gamma_2 = \text{Im}\rho_2$ .

$$D_{\Gamma, p_0} = \{z \in \mathbb{B}^2 : d(z, p_0) \leq d(\gamma z, p_0) \forall \gamma \in \Gamma\}$$

We will assume  $D_{\Gamma, p_0}$  has non empty interior (hard to prove!)

Key:

1. When no nontrivial element of  $\Gamma$  fixes  $p_0$ , this gives a *fundamental domain* for the action of  $\Gamma$ .
2. Otherwise, get a fundamental domain for a coset decomposition (cosets of  $\text{Stab}_{\Gamma} p_0$  in  $\Gamma$ ).

More subtle:

1. Beware these often have infinitely many faces (Phillips, Goldman-Parker)
2. Depend heavily on the *center*  $p_0$ .

## Back to Dirichlet domains

To see that  $\rho_2$  does the job, one way is to study **Dirichlet/Ford domains** for  $\Gamma_2 = \text{Im}\rho_2$ .

$$D_{\Gamma, p_0} = \{z \in \mathbb{B}^2 : d(z, p_0) \leq d(\gamma z, p_0) \forall \gamma \in \Gamma\}$$

We will assume  $D_{\Gamma, p_0}$  has non empty interior (hard to prove!)

Key:

1. When no nontrivial element of  $\Gamma$  fixes  $p_0$ , this gives a *fundamental domain* for the action of  $\Gamma$ .
2. Otherwise, get a fundamental domain for a coset decomposition (cosets of  $\text{Stab}_{\Gamma} p_0$  in  $\Gamma$ ).

More subtle:

1. Beware these often have infinitely many faces (Phillips, Goldman-Parker)
2. Depend heavily on the *center*  $p_0$ .

## Back to Dirichlet domains

To see that  $\rho_2$  does the job, one way is to study **Dirichlet/Ford domains** for  $\Gamma_2 = \text{Im}\rho_2$ .

$$D_{\Gamma, p_0} = \{z \in \mathbb{B}^2 : d(z, p_0) \leq d(\gamma z, p_0) \forall \gamma \in \Gamma\}$$

We will assume  $D_{\Gamma, p_0}$  has non empty interior (hard to prove!)

Key:

1. When no nontrivial element of  $\Gamma$  fixes  $p_0$ , this gives a *fundamental domain* for the action of  $\Gamma$ .
2. Otherwise, get a fundamental domain for a coset decomposition (cosets of  $\text{Stab}_{\Gamma} p_0$  in  $\Gamma$ ).

More subtle:

1. Beware these often have infinitely many faces (Phillips, Goldman-Parker)
2. Depend heavily on the *center*  $p_0$ .

## Poincaré polyhedron theorem

Important tool for proving that  $D_{\Gamma,p_0}$  has non-empty interior.

Use  $D_{F,p_0}$  instead of  $D_{\Gamma,p_0}$  for some subset  $F \subset \Gamma$ .  
[In simplest situations,  $F$  is *finite*].

Assume

- ▶  $F$  generates  $\Gamma$ ;
- ▶  $F = F^{-1}$  and opposite faces are isometric;
- ▶ Cycle conditions on ridges (faces of codimension 2)
- ▶ Cycles of infinite vertices are parabolic

Then the group  $\Gamma$  is **discrete** and we get

- ▶ An explicit group presentation  $\langle F | R \rangle$  where  $R$  are cycle relations.
- ▶ A list of orbits of fixed points.

# Dirichlet/Ford domains

Two natural choices for the center:

- ▶ Fixed point of  $G_1$  (unipotent)  $\rightsquigarrow$  Ford domain
- ▶ Fixed point of  $G_2$  (regular elliptic)  $\rightsquigarrow$  Dirichlet domain

Dirichlet:  $\partial_\infty D_\Gamma$  is (topologically!) a **solid torus**.

Ford:  $\partial_\infty D_\Gamma$  is a **pinched solid torus** (horotube).

# Computational techniques

The key is to be able to **prove** the combinatorics of Dirichlet/Ford polyhedra.

Need to solve a system of quadratic inequalities in four variables.

- ▶ Guess faces and incidence by numerical computations (grids in parameters for intersections of two bisectors)
- ▶ To prove your guess:
  - ▶ Exact computation in appropriate number field, or
  - ▶ Use genericity

# Deformations

Using real  $(3, 3, 4)$ -triangle groups, one gets a 1-parameter family of deformations, where the unipotent element becomes elliptic with eigenvalues  $(1, \zeta, \bar{\zeta})$ ,  $|\zeta| = 1$ .

These deformations give complete spherical CR structures on  $(k, 1)$ -surgeries of the figure eight knot (with  $k \geq 5$ ).

Rank 1 boundary unipotent

## Other examples

Hyperbolic manifolds with low complexity (up to 3 tetrahedra), and representations into  $PU(2, 1)$  with

**Unipotent** and **Rank 1**,

boundary holonomy.

List from Falbel, Koseleff and Rouiller (2013):

m004 =  $4_1$  knot

m009

m015 =  $5_2$  knot

Same seems to work:

- ▶ Dirichlet domains with finitely many faces (for well-chosen center)
- ▶ The image groups are triangle groups.
