# The DNF Exception Problem 

Dhruv Mubayi* György Turán ${ }^{\dagger}$ Yi Zhao ${ }^{\ddagger}$<br>Department of Mathematics, Statistics, and Computer Science<br>University of Illinois at Chicago, Chicago, IL 60607

#### Abstract

Given a disjunctive normal form (DNF) expression $\varphi$ and a set $A$ of vectors satisfying the expression, called the set of exceptions, we would like to update $\varphi$ to get a new DNF which is false on $A$, and otherwise is equivalent to $\varphi$. Is there an algorithm with running time polynomial in the number of variables, the size of the original formula and the number of exceptions, which produces an updated formula of size bounded by a certain type of function of the same parameters?

We give an efficient updating algorithm, which shows that the previously known best upper bound for the size of the updated expression is not optimal in order of magnitude. We then present a lower bound for the size of the updated formula in terms of the parameters, which is the first known lower bound for this problem. We also consider the special case (studied previously in the complexity theory of disjunctive normal forms) where the initial formula is identically true, and give efficient updating algorithms, providing new upper bounds for the size of the updated expression.

## 1. Introduction

The problem of efficiently updating a rule in order to incorporate negative information comes up in many applications. Areas dealing with this issue from different angles include machine learning, computational learning theory, nonmonotonic logic, belief revision, databases, term rewriting and logic programming. We consider this question in the context of propositional logic, by looking at the basic case of disjunctive normal forms.
A DNF over the variables $x_{1}, \ldots, x_{n}$ is a disjunction of terms, which are conjunctions of literals (variables or their negations). The set of vectors satisfying a DNF $\varphi$ is denoted by $T(\varphi)$; the size of $\varphi$ is the number of its terms. The minimal size of any DNF for a Boolean function $f$ is denoted by $\operatorname{Cov}(f)$.
We think of a DNF $\varphi$ as a database, representing, for example, a set of instances for which a certain property holds. Assume that the database needs to be revised, as there is a set of instances

[^0]$A \subseteq T(\varphi)$, called the set of exceptions to $\varphi$, which turn out not to have the property represented by $\varphi$. The objective, then, is to compute a representation of the modified database. In other words, we would like to compute a new DNF $\psi$ representing the Boolean function $\varphi \wedge \neg \chi_{A}$, where $\chi_{A}$ is the characteristic function of $A$. We refer to this computational problem as the DNF exception problem. (Note that besides deleting vectors from $T(\varphi)$, one could also consider the case of adding vectors to $T(\varphi)$. This can be handled in a straightforward manner by adding distinct terms for each vector, and so it is not discussed any further.)

Finding a shortest representation of $\psi$ is easily seen to include the problem of DNF minimization, which is known to be hard to solve exactly or approximately [22, 23]. Motivated by the connection of this problem to computational learning theory (see below in more detail), we are interested in a different criterion: finding efficient algorithms producing a DNF $\psi$ of size bounded by a (possibly slowly increasing) function of the number of variables, the size of the original DNF, and the number of exceptions.

We would like to determine the function

$$
X C(n, m, r)=\max \left\{\operatorname{Cov}\left(\varphi \wedge \neg \chi_{A}\right)\right\}
$$

where the maximum is taken over all $n$-variable DNFs $\varphi$ with at most $m$ terms and all $A \subseteq T(\varphi)$ with $|A| \leq r$. In other words, $X C(n, m, r)$ is the maximal number of terms needed in an optimal DNF for a Boolean function obtained by deleting at most $r$ vectors from an at most $m$-term DNF over the variables $x_{1}, \ldots, x_{n}$. We are also interested in finding an efficient updating algorithm that produces a DNF of size close to this bound.

The DNF exception problem was first studied by Zhuravlev and Kogan [14, 15, 24] in the special case $m=1$, in the context of the complexity theory of disjunctive normal forms. If the initial DNF consists of a single term then it can be considered to be the whole cube, and thus determining $X C(n, 1, r)$ is equivalent to determining the maximal DNF complexity of $n$-variable Boolean functions with $r$ false points. In [24] it is shown that if $r=\log n-\omega(n)$, where $\omega(n) \rightarrow \infty$ arbitrarily slowly, then $X C(n, 1, r)=(1+o(1)) n$, and it is stated ${ }^{1}$ that

$$
\begin{equation*}
X C(n, 1, r) \leq \frac{1}{2} n \cdot r \tag{1}
\end{equation*}
$$

[14] gives lower bounds for small $r$, and [15] gives an upper bound of the form $O\left(\frac{n \cdot r}{\log n}\right)$ for almost all sets if $r$ is in the range $\log n<r=o\left(2^{n / 2}\right)$. Recently D'yakonov $[8,9,10]$ obtained new results on this problem, with emphasis on getting efficient updating algorithms for small values of $r$.

The general DNF exception problem was first considered by Board and Pitt [6] in their work on the relationship between PAC learnability and Occam algorithms. (An Occam algorithm is a learning algorithm that performs data compression in a certain sense. As we do not use these notions, we omit the definitions. See [13] for general background in computational learning theory, and Li , Tromp and Vitányi [18] for more recent work on this relationship). The conjecture, implicit in [6], is that there is no upper bound for $X C(n, m, r)$ of the form

$$
\begin{equation*}
p(n, m, \log r)+q(n, \log m, \log r) \cdot r \tag{2}
\end{equation*}
$$

[^1]where $p$ and $q$ are arbitrary polynomials (in their terminology, DNF are not strongly closed under exception lists). If the conjecture is false, i.e., there is an upper bound of the form (2) for $X C(n, m, r)$, and there is an efficient (polynomial in $n, m$ and $r$ ) algorithm producing an updated formula of size bounded by (2), then it would follow that the existence of an Occam algorithm for DNF is necessary for the PAC learnability of DNF. It is known that the existence of an Occam algorithm is sufficient for PAC learnability in general [5]. We note that the efficient learnability of DNF, both in the PAC and the equivalence and membership query model [12], is one of the main open problems in computational learning theory.
The notion of closure under exception lists comes up in computational learning theory in a different context as well, in the work of Angluin and Krikis [2, 3] on learning with membership and equivalence queries which may contain lies. They give the general upper bound
\[

$$
\begin{equation*}
X C(n, m, r) \leq n m r . \tag{3}
\end{equation*}
$$

\]

The proof of (3) in [2,3] gives an efficient algorithm to produce an updated formula of size bounded by (3). It is implicit in a remark of Angluin and Kriksis that (1) immediately gives an improvement of (3) by a factor $\frac{1}{2}$, but for their purposes it is sufficient to have (3), which has a short proof. It may be the case that (3) is 'almost optimal'. This would imply that, indeed, DNF are not strongly closed under exception lists. As far as we know, there are no previous lower bounds for $X C(n, m, r)$.

Now we turn to the description of the results of this paper. All our positive results give upper bounds for $X C(n, m, r)$ and, at the same time, also provide efficient algorithms to produce an updated formula of size within the stated bound. In the formulation of these results, and their proofs, we only mention the upper bounds, as the algorithms themselves are then easily derived. The negative results give lower bounds for $X C(n, m, r)$.
Our first result shows that the upper bound (3) is not optimal up to a constant factor. The bound improves over (3) by a factor of the order $\frac{\log n}{n}$ when $r$ is exponentially large.
Theorem 1. Suppose that $r \geq n$. Then

$$
X C(n, m, r) \leq\left\lceil\frac{m}{\lfloor\log r / \log n\rfloor}\right\rceil r(n+1)
$$

Now we turn to lower bound results for $X C(n, m, r)$. First, we observe the following simple linear lower bounds:

Proposition 2. a) $X C(n, 1,1) \geq n$,
b) $X C(n, m, r) \geq m$ for $r \leq m \leq 2^{n-2}$,
c) $X C(n, 1, r) \geq \frac{r}{2}$.

We obtain much stronger lower bounds in Theorem 3 and 4 below, where Theorem 3 Part a) shows that (3) is in fact sharp up to a constant factor in the special case $r=1$. We write $\binom{n}{\leq a}=\binom{n}{0}+\binom{n}{1}+\ldots+\binom{n}{a}$. In the statements (and proofs) of these theorems, we omit floor and ceiling symbols.

## Theorem 3.

a) For every $0<\varepsilon<1 / 4$ there is an $n_{0}$ such that for any $n \geq n_{0}$ and $m \leq\left(e^{\frac{2 \varepsilon^{2}}{27} n}\right) / 4$,

$$
X C(n, m, 1) \geq\left(\frac{1}{4}-\varepsilon\right) n m
$$

b) For any $0<\lambda<\delta<1$ satisfying $\delta^{2}+3 \lambda<\delta$, there is an $n_{0}$ such that for any $n \geq n_{0}$, $m \leq\left(e^{\frac{\lambda^{2}}{3 \delta} n}\right) / 4$ and $0 \leq \alpha<\min \left\{\delta^{2}+3 \lambda, \delta-\delta^{2}-3 \lambda\right\}$,

$$
\begin{equation*}
X C\left(n, m,\binom{n}{\leq \alpha n}\right) \geq m \frac{\binom{\delta n}{\alpha n}}{\binom{\delta^{2} n+3 \lambda n}{\alpha n}} . \tag{4}
\end{equation*}
$$

After selecting appropriate $\lambda$ and $\delta$ in Theorem 3 Part b), we obtain the following lower bound.
Theorem 4. For any $0<\varepsilon<1 / 3$, there exist $\alpha>0$, and $n_{0}$ such that

$$
X C(n, m, r) \geq m r^{\frac{1}{3}-\varepsilon}
$$

for every $n \geq n_{0}$ and $m=r=\binom{n}{\leq \alpha n}$.

We now present improved upper bounds for the special case $m=1$ considered in the above mentioned papers $[8,9,10,14,15,24]$. Theorem $5 a$ ) is a slight improvement over (1). This improvement is of interest as it is sharp for $r=n$, and thus it gives some evidence for a general conjecture for the exact value of $X C(n, 1, r)$, when $r$ is a binomial coefficient (see Section 4). Theorem $5 b$ ) improves the upper bound in (1) for large values of $r$.

Theorem 5. a) For $n \geq 2$ and $r \geq 2$

$$
X C(n, 1, r) \leq \frac{n-1}{2} r+1
$$

b)

$$
X C(n, 1, r) \leq\left(n-\left\lceil\log _{2} r\right\rceil+1\right) r
$$

Note that if $r<2^{(n+3) / 2}$ then Part a) gives a better bound, otherwise Part b) gives a better bound.

We use the following notations in this paper. We write $\{0,1\}^{n}$ for the $n$-dimensional hypercube. A subcube (or simply cube) of $\{0,1\}^{n}$ is represented by a sequence of length $n$, consisting of 0 's, 1 's and ${ }^{*}$ 's. The number of the ${ }^{*}$ 's is called the dimension of the cube. Clearly the vectors satisfying a conjunction form a subcube, where 0's (resp. 1's) correspond to negated (resp. unnegated) variables, and *'s correspond to variables which do not occur in the conjunction, either negated or unnegated. Thus, for example, if $n=4$, then the conjunction $x_{2} \wedge \bar{x}_{4}$ can also be written as $* 1 * 0$. We (ab)use the terminology of a DNF for a Boolean function, or a cube cover of a subset
of $\{0,1\}^{n}$ interchangeably, whichever is more convenient. Thus, corresponding to the definition of $\operatorname{Cov}(f)$ in the beginning of the paper, $\operatorname{Cov}(B)$ denotes the minimal number of cubes covering a set $B \subseteq\{0,1\}^{n}$. Note that in a cube cover of $\varphi \wedge \neg \chi_{A}$, the cubes are not required to be disjoint, but they cannot contain any points in $A$. For a vector $x \in\{0,1\}^{n}$, the weight of $x$ is the number of ones in $x$. Let $W_{\ell}$ (resp. $W_{\leq \ell}$ ) be the set of vectors of $\{0,1\}^{n}$ having weight $\ell$ (resp. at most $\ell)$. For a set $S \in[n]=\{1,2, \ldots, n\}$, the characteristic vector $x_{S}$ of $S$ is a vector having 1 at coordinates $i \in S$ and 0 otherwise.

The structure of the rest of the paper is as follows. Section 2 gives the proofs for the general DNF exception problem and Section 3 gives the proofs for the case $m=1$. Section 4 contains some remarks and open problems.

## 2. The general DNF exception problem

We prove Theorem 1 in Section 2.1, and the lower bounds, Proposition 2 and Theorems 3, 4, in Section 2.2. The proof of Theorem 1 is based on partitioning the original set of cubes into groups, replacing each group with a set of disjoint cubes, and deleting the exceptions in each group separately. The proof of Theorem 3 uses a construction which associates a Boolean function to every family of subsets of $[n]$. It is shown that if the family has a certain combinatorial property then a lower bound holds for the number of cubes required to cover the set remaining after all vectors of bounded weight are deleted. A computation providing suitable values for the constants in Theorem 3 proves Theorem 4.

### 2.1. Upper bound

There are standard procedures for writing a union of cubes as a disjoint union of cubes (see, e.g., [20]). These procedures are polynomial in terms of the combined size of the input and the output. Lemma 6 recalls a bound provided by these procedures. It is also known that writing a union of cubes as a disjoint union may require an exponential blowup in the number of cubes [4, 7], although there is a gap between the known lower and upper bounds. We apply these procedures to a small number of cubes, so the resulting algorithm remains polynomial in the size of the input. We use $\bigsqcup$ to emphasize disjoint unions.

## Lemma 6.

a) For any cubes $C, C_{1}, \ldots, C_{t}$, the difference $C \backslash \cup_{i=1}^{t} C_{i}$ can be written as the disjoint union of at most $n^{t}$ cubes.
b) For any cubes $C_{1}, \ldots, C_{t}$, the union $C_{1} \cup \cdots \cup C_{t}$ can be written as the disjoint union of at most $n^{t}$ cubes.

Proof Part a). By induction on $t$, the case $t=1$ holds since, e.g., $\{0,1\}^{m} \backslash \bar{x}_{1} \wedge \ldots \wedge \bar{x}_{k}$ can be covered by $k$ disjoint cubes $x_{1} \bigsqcup\left(\bar{x}_{1} \wedge x_{2}\right) \bigsqcup \cdots \bigsqcup\left(\bar{x}_{1} \wedge \bar{x}_{2} \wedge \ldots \wedge \bar{x}_{k-1} \wedge x_{k}\right)$. For the induction step
we have

$$
C \backslash \bigcup_{i=1}^{t} C_{i}=\left(C \backslash C_{t}\right) \backslash \bigcup_{i=1}^{t-1} C_{i}=\left(\bigsqcup_{j=1}^{m} D_{j}\right) \backslash \bigcup_{i=1}^{t-1} C_{i}=\bigsqcup_{j=1}^{m}\left(D_{j} \backslash \bigcup_{i=1}^{t-1} C_{i}\right)=\bigsqcup_{j=1}^{m}\left(\bigsqcup_{k=1}^{n_{j}} D_{j, k}\right)
$$

where $m \leq n$ and $n_{j} \leq n^{t-1}$.
Part b) follows from Part a) after writing

$$
\bigcup_{i=1}^{t} C_{i}=\bigsqcup_{i=1}^{t}\left(C_{i} \backslash \bigcup_{j=1}^{i-1} C_{j}\right)
$$

Lemma 7. If $C_{1}, \ldots, C_{s}$ are disjoint cubes and $|A| \leq r$, then

$$
\operatorname{Cov}\left(\left(C_{1} \cup \cdots \cup C_{s}\right) \backslash A\right) \leq s+r n
$$

Proof. Let $r_{i}=\left|C_{i} \cap A\right|$. By (3) with $m=1$ (or Theorem 5), we have $\operatorname{Cov}\left(C_{i} \backslash A\right) \leq n r_{i}$. Hence

$$
\operatorname{Cov}\left(\left(C_{1} \bigsqcup \cdots \bigsqcup C_{s}\right) \backslash A\right) \leq \sum_{i=1}^{s} \max \left(1, r_{i} n\right) \leq \sum_{i=1}^{s}\left(1+r_{i} n\right)=s+r n
$$

Proof of Theorem 1. Given subcubes $C_{1} \cup \cdots \cup C_{m}$ of $\{0,1\}^{n}$, and an exception set $A \subseteq\{0,1\}^{n}$ of size $r$, we want to show

$$
\begin{equation*}
\operatorname{Cov}\left(C_{1} \cup \cdots \cup C_{m} \backslash A\right) \leq\left\lceil\frac{m}{\lfloor\log r / \log n\rfloor}\right\rceil r(n+1) \tag{5}
\end{equation*}
$$

We arbitrarily divide the cubes $C_{i}$ into $\left\lceil\frac{m}{t}\right\rceil$ groups of at most $t$ cubes each, where $t=\lfloor\log r / \log n\rfloor$. We then apply Lemma 6 to obtain a disjoint cube cover (of size at most $n^{t}$ ) of the cubes in each group. Finally when deleting $A$ from each group, we apply Lemma 7 and get a cube cover of size $n^{t}+r n$. The sum of the sizes of the cube covers in all the groups is at most $\left\lceil\frac{m}{t}\right\rceil\left(n^{t}+r n\right)$. The bound (5) follows after substituting for $t$.

### 2.2. Lower bounds

## Proof of Proposition 2.

For Part $a$ ), note that if a cube contains both $(1,0, \ldots, 0)$ and $(0,1,0, \ldots, 0)$, then it must have *'s in its first two positions, and *'s or 0's in the other positions. Thus the cube must contain 0, the all-zero vector as well. Thus $\operatorname{Cov}\left(\{0,1\}^{n} \backslash \mathbf{0}\right) \geq n$, as each unit vector must be covered by a distinct cube. Hence $X C(n, 1,1) \geq n$.

For Part $b$ ), note that the vectors satisfying the ( $n-1$ )-variable parity function $x_{1} \oplus \ldots \oplus x_{n-1}$ in $\{0,1\}^{n}$ form $2^{n-2}$ one-dimensional subcubes of pairwise distance at least 2 . We take $m$ of these subcubes and remove $r$ vectors, each from a different subcube. The remaining set still requires $m$ cubes to be covered, thus $X C(n, m, r) \geq m$.
For Part $c$ ), suppose that $2^{i-1} \leq r<2^{i}$. We delete all vectors of even weight from a subcube $C$ of dimension $i$ and $r-2^{i-1}$ vectors from $\{0,1\}^{n} \backslash C$. The remaining $2^{i-1}>r / 2$ vectors in $C$ have odd weights, and each of them must be covered by a different cube.

Now we describe the combinatorial construction used in the proof of Theorem 3. For a set $S \subseteq[n]$, we denote by $C u b e(S)$ the cube obtained by changing all 1's in its characteristic vector $x_{S}$ to ${ }^{*}$ 's. Recall that the Turán number $T(d, u, v)$ is the minimal size of a family of $v$-subsets of $[d]$ such that every $u$-subset of $[d]$ contains at least one subset from the family, where $v \leq u \leq d$ (see, e.g., [11]). Determining $T(d, u, v)$ is a major open problem in extremal combinatorics, but we only use the trivial case $T(d, u+1,1)=d-u$ and the simple bound (see, e.g., [11])

$$
\begin{equation*}
T(d, u, v) \geq \frac{\binom{d}{v}}{\binom{u}{v}} \tag{6}
\end{equation*}
$$

Lemma 8. Given nonnegative integers $\ell \leq t<d$, let $S_{1}, \ldots, S_{m}$ be subsets of $[n]$ such that $\left|S_{i}\right| \geq d$ and $\left|S_{i} \cap S_{j}\right| \leq t$ for every $1 \leq i<j \leq m$. Then

$$
\operatorname{Cov}\left(\bigcup_{i} C u b e\left(S_{i}\right) \backslash W_{\leq \ell}\right) \geq m T(d, t+1, \ell+1)
$$

The following claim is the first step towards the proof of Lemma 8.
Proposition 9. Let $S_{1}, \ldots, S_{m}$ be subsets of $[n]$ such that $\left|S_{i} \cap S_{j}\right| \leq t$ whenever $i \neq j$. If $x \in C u b e\left(S_{i}\right)$ and $y \in C u b e\left(S_{j}\right)(i \neq j)$ are two vectors of weight $t+1$, then there is no cube $C \subseteq \bigcup_{i} C u b e\left(S_{i}\right)$ containing both $x$ and $y$.

Proof. Suppose instead, that $x, y \in C$ for some cube $C \subseteq \bigcup_{i} C u b e\left(S_{i}\right)$. Then, since $C$ is a cube, the vector $x \vee y$ (the componentwise $\vee$ of $x$ and $y$ ) also belongs to $C$. As $C \subseteq \bigcup_{i} C u b e\left(S_{i}\right)$, there exists $1 \leq k \leq m$ such that $x \vee y \in C u b e\left(S_{k}\right)$. Recall that $C u b e(E)$ is a cube having *'s at coordinates $\ell \in E$ and 0 otherwise. Hence $C u b e\left(S_{i}\right)$ has ${ }^{*}$ 's wherever $x$ has a 1 , while $C u b e\left(S_{k}\right)$ has *'s wherever $x \vee y$ has a 1. Therefore $C u b e\left(S_{i}\right)$ and $C u b e\left(S_{k}\right)$ have at least $t+1$ (the weight of $x$ ) common *'s, or $\left|S_{k} \cap S_{i}\right| \geq t+1$. But clearly $k \neq i$ (because $x \vee y$ has 1's outside $S_{i}$ ), a contradiction.

Proof of Lemma 8. From Proposition 9 we know that vectors of weight $t+1$ in different sets Cube $\left(S_{i}\right)$ have to be covered by different cubes. Let $B_{i}$ denote the set of vectors of weight $t+1$ in Cube $\left(S_{i}\right)$, for $1 \leq i \leq m$. Lemma 8 follows if we show that covering all the points from $B_{i}$ by cubes disjoint from $W_{\leq \ell}$ requires at least $T(d, t+1, \ell+1)$ cubes.
In fact, consider a cube $C$ covering some points from $B_{i}$, which is disjoint from $W_{\leq \ell}$. Since Cube $\left(S_{i}\right)$ has 0's outside $S_{i}$, we may assume w.l.o.g that $C$ also has 0's outside $S_{i}$. Indeed, as $C$
contains points from $B_{i}$, it cannot have 1's outside $S_{i}$; if it has *'s outside $S_{i}$ then these can be changed to 0 's without losing any points from $B_{i}$. Furthermore, $C$ must have at least $\ell+1$ 1's, otherwise it contains a vector of weight at most $\ell$. After changing some 1's to *'s if necessary, we may assume that $C$ has exactly $\ell+1$ 's inside $S_{i}$. Then $C$ contains a vector $v \in C u b e\left(S_{i}\right)$ of weight $t+1$ if and only if the set of coordinates at which $C$ equals 1 is a subset of the set of coordinates at which $v$ equals 1 .

Therefore the sets of size $\ell+1$ associated with the cubes covering $B_{i}$ have the property that every size $t+1$ subset of $S_{i}$ contains at least one of them. The minimal number of such sets is exactly the Turán number $T(d, t+1, \ell+1)$.
The following proposition follows by simple probabilistic arguments.
Proposition 10. Given $0<\lambda<\delta<1$, for sufficiently large $n$, if

$$
m<\min \left\{\left(e^{\frac{\lambda^{2}}{3 \delta} n}\right) / 4, e^{\frac{\lambda^{2}}{6 \delta^{2}} n}\right\}
$$

then there exist $(\delta n)$-element subsets $A_{1}, A_{2}, \ldots, A_{m}$ such that $\left|A_{i} \cap A_{j}\right| \leq\left(\delta^{2}+3 \lambda\right) n$ for all $i \neq j$.
Proof. Assume that $n$ is sufficiently large. We first obtain random subsets $A_{1}^{\prime}, \ldots, A_{m}^{\prime}$ of $[n]$ as follows. For each $j \leq n$, we let $j$ be a member of $A_{i}^{\prime}$ with probability $\delta$. Thus the expectation $\operatorname{Exp}\left(\left|A_{i}^{\prime}\right|\right)=\delta n$ for every $A_{i}^{\prime}$ and $\operatorname{Exp}\left(\left|A_{i}^{\prime} \cap A_{j}^{\prime}\right|\right)=\delta^{2} n$ for every pair $A_{i}^{\prime} \neq A_{j}^{\prime}$. Let $B I N(n, p)$ denote the sum of $n$ independent variables, each equal to 1 with probability $p$ and 0 otherwise. The Chernoff bound (see, e.g., [1] Theorem A.11) gives

$$
\operatorname{Pr}(|B I N(n, p)-p n|>t)<2 e^{-t^{2} / 3 p n} \quad \text { and } \quad \operatorname{Pr}(B I N(n, p)>p n+t)<e^{-t^{2} / 3 p n}
$$

We therefore have

$$
\operatorname{Pr}\left(\left|\left|A_{i}^{\prime}\right|-\delta n\right|>\lambda n\right)<2 e^{-\frac{\lambda^{2}}{3 \delta} n} \quad \text { and } \quad \operatorname{Pr}\left(\left|A_{i}^{\prime} \cap A_{j}^{\prime}\right|>\delta^{2} n+\lambda n\right)<e^{-\frac{\lambda^{2}}{3 \delta^{2}} n}
$$

When $m<\min \left\{\left(e^{\frac{\lambda^{2}}{3 \delta} n}\right) / 4, e^{\frac{\lambda^{2}}{6 \delta^{2}} n}\right\}$, we have

$$
2 m e^{-\frac{\lambda^{2}}{3 \delta} n}+\binom{m}{2} e^{-\frac{\lambda^{2}}{3 \delta^{2}} n}<\frac{1}{2}+\frac{1}{2}=1 .
$$

Then there are sets $A_{1}^{\prime}, \ldots, A_{m}^{\prime}$ satisfying $\left|\left|A_{i}^{\prime}\right|-\delta n\right| \leq \lambda n$ for all $i$ and $\left|A_{i}^{\prime} \cap A_{j}^{\prime}\right| \leq\left(\delta^{2}+\lambda\right) n$ for all $i \neq j$. After adding or removing at most $\lambda n$ elements from each $A_{i}^{\prime}$, we obtain new sets $A_{1}, \ldots, A_{m}$ of size exactly $\delta n$ and for all $i \neq j$,

$$
\left|A_{i} \cap A_{j}\right| \leq\left(\delta^{2}+\lambda\right) n+\lambda n+\lambda n=\delta^{2} n+3 \lambda n
$$

## Proof of Theorem 3.

To prove Part a), given $0<\varepsilon<1 / 4$, we apply Proposition 10 with $\delta=1 / 2$ and $\lambda=\varepsilon / 3$. When $m<\left(e^{\frac{\lambda^{2}}{3 \delta} n}\right) / 4=\left(e^{\frac{2 \varepsilon^{2}}{27} n}\right) / 4$, we obtain $(n / 2)$-element sets $A_{1}, \ldots, A_{m}$ such that $\left|A_{i} \cap A_{j}\right| \leq$
$(1 / 4+\varepsilon) n$ for all $i \neq j$. Next we apply Lemma 8 to $A_{1}, \ldots, A_{m}$ where $d=n / 2, t=(1 / 4+\varepsilon) n$ and $\ell=0$ (here we need $\varepsilon<1 / 4$ to guarantee $t<d$ ). It follows directly from the definition that $T(d, t+1,1)=d-t$. Thus we conclude that

$$
X C(n, m, 1) \geq \operatorname{Cov}\left(\cup_{i=1}^{m} C u b e\left(A_{i}\right) \backslash \mathbf{0}\right) \geq m T\left(\frac{n}{2}, \frac{n}{4}+\varepsilon n+1,1\right)=\left(\frac{1}{4}-\varepsilon\right) n m
$$

To prove Part b), we first apply Proposition 10 and obtain ( $\delta n$ )-element sets $A_{1}, \ldots, A_{m}$ such that $\left|A_{i} \cap A_{j}\right| \leq\left(\delta^{2}+3 \lambda\right) n$ for all $i \neq j$. Next we apply Lemma 8 to $A_{i}$ in which $d=\delta n, t=\left(\delta^{2}+3 \lambda\right) n$ and $\ell=\alpha n$ (here we need $\alpha \leq \delta^{2}+3 \lambda<\delta$ and $n$ large to guarantee that $\ell \leq t<d$ ). This gives

$$
X C\left(n, m,\binom{n}{\leq \alpha n}\right) \geq m T\left(\delta n, \delta^{2} n+3 \lambda n+1, \alpha n+1\right)
$$

The desired lower bound now follows from (6),

$$
X C\left(n, m,\binom{n}{\leq \alpha n}\right) \geq m \frac{\binom{\delta n}{\alpha n+1}}{\binom{\delta^{2} n+3 \lambda n+1}{\alpha n+1}}=m \frac{\binom{\delta n}{\alpha n}}{\binom{\delta^{2} n+3 \lambda n}{\alpha n}} \frac{\delta n-\alpha n}{\delta^{2} n+3 \lambda n+1}>m \frac{\binom{\delta n}{\alpha n}}{\binom{\delta^{2} n+3 \lambda n}{\alpha n}}
$$

where the last inequality uses the assumption that $\alpha<\delta-\delta^{2}-3 \lambda$ and $n$ is large.

## Proof of Theorem 4.

Let us first recall the entropy function

$$
h(x)=-x \ln x-(1-x) \ln (1-x), \quad 0<x<1
$$

(for the convenience of later computation, we use $l n$, instead of $l o g_{2}$ ).
Our proof consists of two steps. In Step 1, we assume that $\delta, \lambda, \alpha$ satisfy the condition of Theorem 3 and in addition, $\alpha \leq \min \left\{1 / 3,\left(\delta^{2}+3 \lambda\right) / 2\right\}$. The goal of this step is to prove

$$
\begin{equation*}
X C\left(n, m,\binom{n}{\leq \alpha n}\right)>m\binom{n}{\leq \alpha n}^{\gamma_{0}} \tag{7}
\end{equation*}
$$

where

$$
\gamma_{0}=\gamma_{0}(\delta, \lambda, \alpha)=\frac{\delta h\left(\frac{\alpha}{\delta}\right)-\left(\delta^{2}+3 \lambda\right) h\left(\frac{\alpha}{\delta^{2}+3 \lambda}\right)}{h(\alpha)}
$$

In Step 2 we will specify the values of $\lambda, \delta, \alpha$ which lead to the conclusion of Theorem 4.
Step 1: Using Stirling's formula, we write

$$
\begin{equation*}
\binom{n}{\alpha n}=\frac{1+o(1)}{\sqrt{2 \pi \alpha(1-\alpha) n}} e^{n h(\alpha)}, \text { as } n \rightarrow \infty \tag{8}
\end{equation*}
$$

Applying (8) twice and using the assumption $\alpha \leq\left(\delta^{2}+3 \lambda\right) / 2$, we have

$$
\frac{\binom{\delta n}{\alpha n}}{\binom{\delta^{2} n+3 \lambda n}{\alpha n}}=(1+o(1)) \sqrt{\frac{\delta\left(\delta^{2}+3 \lambda-\alpha\right)}{(\delta-\alpha)\left(\delta^{2}+3 \lambda\right)}} \frac{e^{\delta n h\left(\frac{\alpha}{\delta}\right)}}{e^{\left(\delta^{2}+3 \lambda\right) n h\left(\frac{\alpha}{\delta^{2}+3 \lambda}\right)}}>\frac{1}{\sqrt{2}} \cdot e^{\delta n h\left(\frac{\alpha}{\delta}\right)-\left(\delta^{2}+3 \lambda\right) n h\left(\frac{\alpha}{\delta^{2}+3 \lambda}\right)} .
$$

Applying this to (4) and using the definition of $\gamma_{0}$, we have

$$
X C\left(n, m,\binom{n}{\leq \alpha n}\right)>m \frac{1}{\sqrt{2}} \cdot e^{\left(\delta h\left(\frac{\alpha}{\delta}\right)-\left(\delta^{2}+3 \lambda\right) h\left(\frac{\alpha}{\delta^{2}+3 \lambda}\right)\right) n}=\frac{m}{\sqrt{2}}\left(e^{n h(\alpha)}\right)^{\gamma_{0}}
$$

For any $0<c<1$, we know that $x h\left(\frac{c}{x}\right)$ is an increasing function for $x>c$. Therefore $\delta^{2}+3 \lambda<$ $\delta<1$ implies that $0<\gamma_{0}<1$ and in particular, $(\pi \alpha(1-\alpha) n / 2)^{\gamma_{0}}>8$ for large $n$. Applying (8) again, we finally obtain

$$
X C\left(n, m,\binom{n}{\leq \alpha n}\right)>\frac{m}{\sqrt{2}} 2 \sqrt{2}\left(\frac{2}{\sqrt{2 \pi \alpha(1-\alpha) n}} e^{n h(\alpha)}\right)^{\gamma_{0}}>2 m\binom{n}{\alpha n}^{\gamma_{0}}>m\binom{n}{\leq \alpha n}^{\gamma_{0}}
$$

where the last inequality holds because $\gamma_{0}<1$ and $\binom{n}{\leq \alpha n} \leq 2\binom{n}{\alpha n}$ for $\alpha \leq 1 / 3$.
Step 2: We specify the values of $\lambda, \delta, \alpha$ which lead to the conclusion of Theorem 4 . In order to have $\binom{n}{\leq \alpha n}=r=m<\left(e^{\frac{\lambda^{2}}{3 \delta} n}\right) / 4$ for all large $n$, it suffices to have $h(\alpha) \leq \frac{\lambda^{2}}{3 \delta}$ or $\lambda \geq \sqrt{3 \delta h(\alpha)}$. We thus let $\delta=\alpha^{p}, \lambda=\sqrt{3 \alpha^{p} h(\alpha)}$ and $\alpha>0$ be very small. It is easy to see that all the constraints in Theorem 3 Part b) and Step 1 hold, i.e., $\delta^{2}+3 \lambda<\delta$ and $\alpha<\min \left\{1 / 3,\left(\delta^{2}+3 \lambda\right) / 2, \delta-\delta^{2}-3 \lambda\right\}$. We claim that it suffices to have

$$
\begin{equation*}
\lim _{\alpha \rightarrow 0} \gamma_{0}\left(\alpha^{p}, \sqrt{3 \alpha^{p} h(\alpha)}, \alpha\right)=p \quad \text { for every } p<1 / 3 \tag{9}
\end{equation*}
$$

In fact, assume (9) holds and $0<\varepsilon<1 / 3$. We let $p=1 / 3-\varepsilon / 2$ and choose $\alpha>0$ small enough such that $\gamma_{0}\left(\alpha^{p}, \sqrt{3 \alpha^{p} h(\alpha)}, \alpha\right) \geq 1 / 3-\varepsilon$ and all the constraints hold. The desired bound in Theorem 4 immediately follows from (7).

To facilitate the proof of (9), we define

$$
\gamma(\delta, \alpha)=\gamma_{0}(\delta, \sqrt{3 \delta h(\alpha)}, \alpha), \quad \gamma_{1}(\delta, \alpha)=\gamma_{0}(\delta, 0, \alpha)
$$

and prove the following propositions.
Proposition 11. $\lim _{\alpha \rightarrow 0} \gamma_{1}\left(\alpha^{p}, \alpha\right)-\gamma\left(\alpha^{p}, \alpha\right)=0$ for any $p<1 / 3$.
Proposition 12. $\lim _{\alpha \rightarrow 0} \gamma_{1}\left(\alpha^{p}, \alpha\right)=p$ for any $p<1$.

## Proof of Proposition 11.

Since

$$
\gamma_{1}\left(\alpha^{p}, \alpha\right)-\gamma\left(\alpha^{p}, \alpha\right)=\frac{\left(\alpha^{2 p}+3 \sqrt{3 \alpha^{p} h(\alpha)}\right) h\left(\frac{\alpha}{\alpha^{2 p}+3 \sqrt{3 \alpha^{p} h(\alpha)}}\right)-\alpha^{2 p} h\left(\frac{\alpha}{\alpha^{2 p}}\right)}{h(\alpha)}
$$

it suffices to show that $\Gamma:=\left(\alpha^{2 p}+3 \sqrt{3 \alpha^{p} h(\alpha)}\right) h\left(\frac{\alpha}{\alpha^{2 p}+3 \sqrt{3 \alpha^{p} h(\alpha)}}\right)=\alpha^{2 p} h\left(\alpha^{1-2 p}\right)+o(h(\alpha))$.
Using the Taylor series, we know that as $x \rightarrow 0$

$$
\begin{equation*}
h(x)=-x \ln x+x+o(x)=-x \ln x(1+o(1)) \tag{10}
\end{equation*}
$$

When $p<1 / 3$ we have $h(\alpha)=o\left(\alpha^{3 p}\right)$ and $3 \sqrt{3 \alpha^{p} h(\alpha)}=o\left(\alpha^{2 p}\right)$. Consequently

$$
h\left(\frac{\alpha}{\alpha^{2 p}+3 \sqrt{3 \alpha^{p} h(\alpha)}}\right)=h\left(\frac{\alpha}{\alpha^{2 p}+o\left(\alpha^{2 p}\right)}\right)=h\left(\alpha^{1-2 p}+o\left(\alpha^{1-2 p}\right)\right) .
$$

Thus

$$
\Gamma=\alpha^{2 p}(1+o(1)) \cdot h\left(\alpha^{1-2 p}+o\left(\alpha^{1-2 p}\right)\right)
$$

Now we need to express $h(x+o(x))$ in terms of $h(x)($ as $x \rightarrow 0)$. Since $\ln x$ is continuous at $x=1$, we have $\ln (x+o(x))=\ln x+o(1)$. This and (10) imply that

$$
\begin{aligned}
h(x+o(x)) & =-(x+o(x)) \ln (x+o(x))+(x+o(x))+o(x) \\
& =-(x+o(x))(\ln x+o(1))+o(x \ln x) \\
& =-x \ln x+o(x \ln x) \\
& =h(x)+o(h(x)) .
\end{aligned}
$$

Therefore

$$
\Gamma=\alpha^{2 p}(1+o(1)) \cdot\left(h\left(\alpha^{1-2 p}\right)+o\left(h\left(\alpha^{1-2 p}\right)\right)\right)=\alpha^{2 p} h\left(\alpha^{1-2 p}\right)+o(h(\alpha))
$$

where the last equality holds because $o\left(\alpha^{2 p} h\left(\alpha^{1-2 p}\right)\right)=o(h(\alpha))$.

## Proof of Proposition 12.

Using (10), we know that as $\alpha \rightarrow 0$,

$$
\begin{aligned}
\alpha^{p} h\left(\alpha^{1-p}\right) & =\alpha^{p}\left(-\alpha^{1-p} \ln \alpha^{1-p}+o\left(\alpha^{1-p} \ln \alpha^{1-p}\right)\right) \\
& =(p-1) \alpha \ln \alpha+o(\alpha \ln \alpha)
\end{aligned}
$$

Consequently

$$
\begin{aligned}
\alpha^{p} h\left(\alpha^{1-p}\right)-\alpha^{2 p} h\left(\alpha^{1-2 p}\right) & =(p-1) \alpha \ln \alpha+o(\alpha \ln \alpha)-((2 p-1) \alpha \ln \alpha+o(\alpha \ln \alpha)) \\
& =-p \alpha \ln \alpha+o(\alpha \ln \alpha)
\end{aligned}
$$

and

$$
\gamma_{1}\left(\alpha^{p}, \alpha\right)=\frac{\alpha^{p} h\left(\alpha^{1-p}\right)-\alpha^{2 p} h\left(\alpha^{1-2 p}\right)}{h(\alpha)}=\frac{-p \alpha \ln \alpha+o(\alpha \ln \alpha)}{h(\alpha)} \rightarrow p \quad \text { as } \alpha \rightarrow 0
$$

The proof of Theorem 4 is now completed.

Remark: It seems that $1 / 3$ is actually the maximum of $\gamma_{0}$ in our range of the parameters. Although we do not prove this, we know that this maximum is not near 1 by the following arguments. First, because $x h(c / x)$ is an increasing function of $x$ and $\lambda \geq \sqrt{3 \delta h(\alpha)}$, we know that $\max \gamma_{0}(\delta, \lambda, \alpha)=\max \gamma(\delta, \alpha)$. Secondly,

$$
\max \gamma(\delta, \alpha) \leq \max _{\alpha \leq \delta^{2}} \gamma_{1}(\delta, \alpha)=\max _{\alpha} \gamma_{1}(\sqrt{\alpha}, \alpha)=\max _{\alpha} \frac{\sqrt{\alpha} h(\sqrt{\alpha})}{h(\alpha)} \leq \max _{0<x<1} \frac{x h(x)}{h\left(x^{2}\right)}=\mathcal{G}
$$

where $\mathcal{G}=\frac{\sqrt{5}-1}{2}=0.618 \ldots$ is the golden ratio.

## 3. The exception problem for a single cube

In this section we consider the special case $m=1$ of the exception problem. It may be assumed w.l.o.g. that the cube is the whole cube $\{0,1\}^{n}$. We write the set $A$ of exception vectors as $\left\{a_{1}, a_{2}, \ldots, a_{r}\right\} \subseteq\{0,1\}^{n}$. We look for a minimal cube cover of $\{0,1\}^{n} \backslash A$.
We will use two particular cubes $E_{i}=x_{i}$, and $O_{i}=\bar{x}_{i} \wedge x_{i+1}$ for $1 \leq i \leq n$ (with cyclic indexing, i.e., $O_{n}=\bar{x}_{n} \wedge x_{1}$ ). If necessary, we may emphasize the dimension $n$ by writing $E_{i}^{n}, O_{i}^{n}$ instead of $E_{i}, O_{i}$.
Let $M$ denote the $r \times n$ matrix whose $i$ th row is $a_{i}$. First, let us make two simple observations.
Observation 1. Switching 0's and 1's within a column, or switching two columns of $M$ does not change the covering number.

Observation 2. If there is a column which is identically 0 or 1 , meaning that $A$ is contained in a half-cube, then a covering may be obtained by taking a minimal covering in the corresponding half-cube and adding the other half-cube. For example, suppose that the $n$th column of $M$ is $\mathbf{0}$ and let $a_{i}^{\prime}$ be the restriction of $a_{i}$ on the first $n-1$ coordinates. If $\{0,1\}^{n-1} \backslash\left\{a_{1}^{\prime}, \ldots, a_{r}^{\prime}\right\}$ has a cover $C_{1}^{\prime} \cup \ldots \cup C_{t}^{\prime}$, then $\{0,1\}^{n} \backslash A$ can be covered by $C_{1} \cup \ldots \cup C_{t} \cup E_{n}$, where $C_{i}=C_{i}^{\prime} \wedge \bar{x}_{n}$.

Proof of Theorem 5, Part $\boldsymbol{a}$ ). To prove $X C(n, 1, r) \leq \frac{n-1}{2} r+1$ for $r \geq 2$, we do induction on $r$ and $n$.
The assertion trivially holds when $n=1$. When $r=2$, using Observation 1 , we may assume that $a_{1}=0$ and $a_{2}=1 \ldots 10 \ldots 0$ (the first $d$ coordinates are 1 's). When $d=1, E_{2} \cup \ldots \cup E_{n}$ is a cover of size $n-1$. When $d>1$, we first observe that $O_{1}^{d}, \ldots, O_{d}^{d}$ is a cover for $\{0,1\}^{d} \backslash\{\mathbf{0}, \mathbf{1}\}$. Next, we apply Observation 2 repeatedly extending this to a cover for $\{0,1\}^{n} \backslash\left\{a_{1}, a_{2}\right\}$ by adding $n-d$ additional cubes. Thus $X C(n, 1,2) \leq d+n-d=n$.
Now assume $r>2$. Let $r_{j}=\left|\left\{1 \leq i \leq r: a_{i j}=0\right\}\right|$ for $j=1, \ldots, n$.
Case 1. There exists a $j_{0}$ such that either $r_{j_{0}}=0$ or $r_{j_{0}}=r$.
Using Observation 1 we may assume $j_{0}=n$. Let $a_{i}^{\prime}$ denote the restriction of $a_{i}$ on the first $n-1$ coordinates. By induction hypothesis, there exists a cube cover of size $m \leq \frac{n-2}{2} r+1$ covering $\{0,1\}^{n-1} \backslash\left\{a_{1}^{\prime}, \cdots, a_{r}^{\prime}\right\}$. As shown in Observation 2, we may extend it to a cover for $\{0,1\}^{n} \backslash\left\{a_{1}, \cdots, a_{r}\right\}$ by adding one more cube. The size of the new cover $m+1$ is at most $\frac{n-2}{2} r+2 \leq \frac{n-1}{2} r+1$ (using $r \geq 2$ ).

Case 2. There exists $j_{0}$ such that $2 \leq r_{j_{0}} \leq r-2$.
Again assume that $j_{0}=n$ and define $a_{i}^{\prime}$ as in Case 1. Let $A_{0}$ denote the set of vectors $a_{i}^{\prime}$ at which $a_{i n}=0$ and $A_{1}=A-A_{0}$. Since $r_{n} \geq 2$ and $r-r_{n} \geq 2$, using induction hypothesis twice, we find cubes $C_{1}^{\prime}, \ldots, C_{m_{1}}^{\prime}$ covering $\{0,1\}^{n} \backslash A_{0}$ and $D_{1}^{\prime}, \ldots, D_{m_{2}}^{\prime}$ covering $\{0,1\}^{n} \backslash A_{1}$, where $m_{1}=(n-2) r_{n} / 2+1$ and $m_{2}=(n-2)\left(r-r_{n}\right) / 2+1$. Therefore $\{0,1\}^{n} \backslash A$ can be covered by $\cup_{i=1}^{m_{1}} C_{i} \bigcup \cup_{i=1}^{m_{2}} D_{i}$ with $C_{i}=C_{i}^{\prime} \wedge \bar{x}_{n}$ and $D_{i}=D_{i}^{\prime} \wedge x_{n}$. The size of this cover, $m_{1}+m_{2}$ is at most $\frac{n-2}{2} r_{n}+1+\frac{n-2}{2}\left(r-r_{n}\right)+1 \leq \frac{n-1}{2} r+1$.

Case 3. For every $j=1, \ldots, n$ either $r_{j}=1$ or $r_{j}=r-1$.

Applying Observation 1, we may assume that $r_{j}=r-1$ for all $j$, i.e., each column of $M$ has exactly one 1 and $r-10$ 's. We consider the following two subcases.

Case 3a. $a_{i} \neq \mathbf{0}$ for all $i$.
In this case we must have $r \leq n$. We may assume that there exist $0=n_{0}<n_{1}<\cdots n_{r-1}<n_{r}=n$ which divide the integer interval $[n]$ into $r$ blocks $B_{1}, B_{2}, \ldots, B_{r}\left(B_{i}=\left[n_{i-1}+1, n_{i}\right]\right)$ such that columns in the $i^{\prime}$ 'th block have a 1 in the $i^{\prime}$ th position:

$$
\begin{aligned}
& a_{1}=\overbrace{1 \cdots 1}^{B_{1}} \begin{array}{cccc}
0 \cdots & \cdots & \cdots 0 \\
a_{2}= & \overbrace{1 \cdots 0}^{B_{2}} & \overbrace{1 \cdots 1} & 0 \cdots \\
a_{n}= & \cdots 0 \\
0 \cdots & \cdots & \cdots 0 & \overbrace{1 \cdots 1}^{B_{r}}
\end{array}
\end{aligned}
$$

A short case analysis (which we omit) shows that $\{0,1\}^{n} \backslash\left\{a_{i}\right\}_{i=1}^{r}$ is covered by the following cubes: $C_{i j}=x_{n_{i}+1} \wedge x_{n_{j}+1}$ for $0 \leq i<j \leq r-1, O_{k}=\bar{x}_{k} \wedge x_{k+1}$ for all $k \neq n_{1}, \ldots, n_{r}$ and $D=\bar{x}_{n_{1}} \wedge \bar{x}_{n_{2}} \wedge \cdots \wedge \bar{x}_{n}$. Hence we get a covering of size $\binom{r}{2}+n-r+1 \leq \frac{n-1}{2} r+1$ (using $r \geq 2$ ).

Case 3b. $a_{i}=\mathbf{0}$ for some $i$.
In this case $r \leq n+1$. When $r=n+1, A$ consists of all the vectors of weight at most 1 . Cubes $x_{i} \wedge x_{j}, 1 \leq i<j \leq n$ give a covering of size $\binom{n}{2}<\frac{n-1}{2}(n+1)+1$. When $r \leq n$, we first assume that $a_{r}=\mathbf{0}$. Similar as in Case 3a, there are $0=n_{0}<n_{1}<\cdots<n_{r-1}=n$ such that $a_{i}(i<r)$ has values 1 exactly in the block $B_{i}=\left[n_{i-1}+1, n_{i}\right]$. It is not hard to see that $\{0,1\}^{n} \backslash A$ is covered by the union of the following cubes: $O_{k}$ for all $k \neq n_{1}, \ldots, n_{r-1}, D_{i}=x_{n_{i-1}+1} \wedge \bar{x}_{n_{i}}$ for $i=1, \ldots, r-1$ and

$$
C_{i j}=* \cdots * \overbrace{1 \cdots 1}^{B_{i}} * \cdots * \overbrace{1 \cdots 1}^{B_{j}} * \cdots *,
$$

for $1 \leq i<j \leq r-1$. Hence we get a covering of size $n-(r-1)+r-1+\binom{r-1}{2}=\binom{r}{2}+n-r+1 \leq$ $\frac{n-1}{2} r+1$ cubes (using $r \geq 2$ ).

Proof of Theorem 5, Part b). We first recall Angluin and Krikis' proof of (3). They used a complete binary tree $T$ of depth $n$ to represent cubes: the root (at level 0 ) is $\{0,1\}^{n}$; for $0 \leq i<n$, a cube $C$ in the $i$ th level has left child $C \wedge x_{i+1}$ and right child $C \wedge \bar{x}_{i+1}$. In other words, the $i$ th level consists of cubes $z_{1} \wedge z_{2} \wedge \cdots \wedge z_{i}$ with $z_{i} \in\left\{x_{i}, \bar{x}_{i}\right\}$ and the leaves are all vectors in $\{0,1\}^{n}$. Consider a set $A$ of an exception vectors. Let $T_{A}$ be the union of paths from the root to all elements in $A$. It is easy to see that the cubes $C$ whose parent is contained in $T_{A}$ but $C \notin T_{A}$ make up a cover of $\{0,1\}^{n} \backslash A$. The size of this cover is equal to the number of vertices with precisely one child in $T_{A}$. Clearly this number is at most $\left|T_{A}\right|<n|A|$, Angluin and Kriķis thus concluded that $X C(n, 1, r) \leq n r$ and consequently (3). The following lemma gives a better (in fact, tight) bound on the number of vertices with one child and Theorem 5 Part $b$ ) thus follows.

Lemma 13. Suppose that $T$ is a binary tree with $r$ leaves, all having depth $n$. Then the number of vertices with one child is at most $(n-\lceil\log r\rceil+1) r$.

Proof of Lemma 13. Suppose that $T$ is a tree that satisfies the hypothesis and has as many nodes with one child as possible. Let $L_{i}$ be the set of vertices in its $i$ th level and $l_{i}=\left|L_{i}\right|$. We observe that for $1 \leq i \leq n-1$, if $l_{i}<l_{i+1}$, then $l_{i-1}=l_{i} / 2$. Otherwise, there must exist $v \in L_{i}$ and $u \in L_{i-1}$ such that $v$ has two children $w, w^{\prime}$ and $u$ has one child. Remove the edge ( $v, w^{\prime}$ ), add a new vertex $v^{\prime}$ in the $i$ th level and add two edges $\left(w^{\prime}, v^{\prime}\right)$ and $\left(v^{\prime}, u\right)$. The new tree $T^{\prime}$ still satisfies the hypothesis and has one more vertex with one child, a contradiction. This means that $\left\{l_{0}, l_{1}, \ldots, l_{n}\right\}=\left\{1,2,4, \ldots, 2^{i}, r, \ldots, r\right\}$, where $i=\lceil\log r\rceil-1$. Consequently the number of vertices with one child is less than $(n-i) r=(n-\lceil\log r\rceil+1) r$.

## 4. Further remarks and open problems

It would be of interest to show that DNF are not strongly closed under exception lists, or to strengthen Theorem 4 by improving the exponent of $r$ in the lower bound. The construction of Theorem 3 uses DNF containing only negated variables. It would be interesting to know, what are the best possible bounds for this class of DNF (or, equivalently, for monotone DNF).
If we delete every vector of weight $k$ from $\{0,1\}^{n}$, then every vector of weight $k-1$ and $k+1$ requires a different cube to cover it, and consequently $X C\left(n, 1,\binom{n}{k}\right) \geq\binom{ n}{k+1}+\binom{n}{k-1}$ for $0 \leq k<n$. Theorem 5, Part $a$ ) implies that this inequality becomes an equality for $k=1$. It is easy to see that the equality holds for $k=0$ as well. We conjecture that this is the case for every $k$, i.e., $X C\left(n, 1,\binom{n}{k}\right)=\binom{n}{k+1}+\binom{n}{k-1}$ for $0 \leq k<n$.
If the exceptions in the DNF exception problem are cubes instead of points then the number of cubes needed to cover the updated set can be exponential in the number of cubes deleted. This is shown by the example $\operatorname{Cov}\left(\{0,1\}^{n} \backslash\left(\left(\overline{x_{1}} \wedge \overline{x_{2}}\right) \vee \cdots \vee\left(\overline{x_{n-1}} \wedge \overline{x_{n}}\right)\right)\right)=2^{\frac{n}{2}}$.
Exception problems could also be studied over other standard machine learning domains, such as first-order logic, geometry and automata. In [21] a quantitative version is given of a special case of the seminal result of Lassez and Marriott [17] over the domain of first-order terms.

Note added in proof In the recent paper M. Alekhnovich, M. Braverman, V. Feldman, A. Klivans, T. Pitassi: Learnability and automatizability, 45. FOCS (2004), 621-630 it is shown that if $N P \neq R P$ then DNF are not properly PAC learnable, solving a longstanding open problem. The proof does not use the Occam algorithm approach discussed in the introduction.
