

# Written Homework # 2 Solution

10/09/08

1. (**20 points**) The challenge of part (a) is not to fall asleep. A part of basic algebra is checking mundane details. Let  $f, g, h \in \mathcal{G}$ .

(a) (**9 pts**) Let  $i \in I$ . Since the binary operation in  $G_i$  is associative

$$\begin{aligned} ((fg)h)(i) &= ((fg)(i))h(i) \\ &= (f(i)g(i))h(i) \\ &= f(i)(g(i)h(i)) \\ &= f(i)((gh)(i)) \\ &= (f(gh))(i). \end{aligned}$$

We have shown that  $(fg)h = f(gh)$ .

Let  $e_i$  be the identity element of  $G_i$  for all  $i \in I$  and define  $e \in \mathcal{G}$  by  $e(i) = e_i$  for all  $i \in I$ . Then

$$(fe)(i) = f(i)e(i) = f(i)e_i = f(i) = e_i f(i) = (ef)(i)$$

for all  $i \in I$  means that  $fe = f = ef$ . Thus  $e$  is an identity element for  $\mathcal{G}$ .

Define  $f' \in \mathcal{G}$  by  $f'(i) = f(i)^{-1}$  for all  $i \in I$ . The calculations

$$(ff')(i) = f(i)f'(i) = f(i)f(i)^{-1} = e_i = e(i)$$

and

$$(f'f)(i) = f'(i)f(i) = f(i)^{-1}f(i) = e_i = e(i)$$

show that  $ff' = e = f'f$ . Therefore  $f$  has an inverse which is  $f'$ .

(b) (**11 pts**) Tables for finite groups have the property that each element of the group must appear exactly once in each row and in each column (cancellation property). We may write  $G = \{e, a, b, c\}$ , where  $e$  is the identity element of  $G$ .

Case 1:  $x^2 = e$  for all  $x \in G$ . Then the table looks like

	e	a	b	c
e	e	a	b	c
a	a	e	·	·
b	b	·	e	·
c	c	·	·	e

We are forced to fill in

the columns (left to right)

	e	a	b	c
e	e	a	b	c
a	a	e	·	·
b	b	<b>c</b>	e	·
c	c	<b>b</b>	·	e

	e	a	b	c
e	e	a	b	c
a	a	e	<b>c</b>	·
b	b	c	e	·
c	c	b	<b>a</b>	e

	e	a	b	c
e	e	a	b	c
a	a	e	c	<b>b</b>
b	b	c	e	<b>a</b>
c	c	b	a	e

Thus the table must be

		e	a	b	c
e		e	a	b	c
a		a	e	c	b
b		b	c	e	a
c		c	b	a	e

$\mathbf{Z}_2 \times \mathbf{Z}_2$  realizes the table. Let  $x = (1, 0)$  and  $y = (0, 1)$ . Set  $z = x + y = (1, 1)$  and  $0 = (0, 0)$ .

Then the table for  $\mathbf{Z}_2 \times \mathbf{Z}_2$  is

		0	x	y	z
0		0	x	y	z
x		x	0	z	y
y		y	z	0	x
z		z	y	x	0

Thus  $f : \mathbf{Z}_2 \times \mathbf{Z}_2 \rightarrow G$  given by

$$f(0) = e, \quad f(x) = a, \quad f(y) = b, \quad f(z) = c$$

is an isomorphism of groups.

*Case 2:*  $x^2 \neq e$  for some  $x \in G$ . We may assume  $a^2 = b \neq e$  (Why?) Thus the table looks like

	e	a	b	c			e	a	b	c
e	e	a	b	c		e	e	a	b	c
a	a	b	.	.	The second row and second column must be filled in	a	a	b	<b>c</b>	<b>e</b> which
b	b	.	.	.		b	b	<b>c</b>	.	.
c	c	.	.	.		c	c	<b>e</b>	.	.

	e	a	b	c			e	a	b	c
e	e	a	b	c		e	e	a	b	c
a	a	b	c	e	and	a	a	b	c	e
b	b	c	<b>e</b>	.		b	b	c	e	<b>a</b>
c	c	e	<b>a</b>	.		c	c	e	a	<b>b</b>

forces

		0	1	2	3
0		0	1	2	3
1		1	2	3	0
2		2	3	0	1
3		3	0	1	2

$\mathbf{Z}_4$  is given by

$$f(0) = e, \quad f(1) = a, \quad f(2) = b, \quad f(3) = c$$

is an isomorphism.

2. (20 points) The condition  $a^2 = e$  for all  $a \in G$  is equivalent to  $a = a^{-1}$  for all  $a \in G$ .

(a) (7 pts) Let  $a, b \in G$ . From  $abab = (ab)^2 = e$  we deduce  $ab = b^{-1}a^{-1} = ba$ .

(b) (13 pts) If  $|G| = 1, 2$  we are done.

**Note:** The condition  $0 \leq i < n$  should have been  $0 < i \leq n$ .

Suppose  $|G| > 2$ . Since  $G$  is abelian  $G$  is not simple; else, since all subgroups of  $G$  are normal by part (a),  $G$  is cyclic and  $G \simeq \mathbf{Z}_2$  as  $G = \langle a \rangle$  for some  $a \in G$  and  $a^2 = e$ . Therefore there is a

(normal) subgroup  $H$  of  $G$  which satisfies  $(e) \neq H \neq G$ . Since  $G$  is finite there is a maximal such subgroup which we call, by slight abuse of notation,  $H$  as well.

From  $|G| = |G/H||H|$  we now conclude that  $1 < |G/H|, |H| < |G|$ . By the Fourth Isomorphism Theorem  $G/H$  is simple. Thus  $G/H$  is cyclic of order 2, by our argument above, which means  $|G : H| = 2$ .

By induction on  $|G|$  there is an  $m \geq 0$  and a chain of subgroups  $(e) = H_0 \subseteq H_1 \subseteq \cdots \subseteq H_m = H$  such that  $|H_i : H_{i-1}| = 2$  for all  $0 < i \leq m$ . Set  $n = m + 1$  and  $G = H_n$ . Thus our conclusion follows by induction on  $|G|$ .

3. **(15 points)** Let  $a \in G$ . Then  $a \in S$  for a unique  $S \in \mathcal{G}$  since  $\mathcal{G}$  partitions  $G$ . Therefore  $\pi : G \rightarrow \mathcal{G}$  given by  $\pi(a) = S$  is a well-defined function.

Now suppose  $b \in \mathcal{G}$  and let  $T \in \mathcal{G}$  satisfy  $b \in T$ . Then  $ab \in ST$  and  $ST \in \mathcal{G}$  by assumption. Therefore  $\pi(ab) = ST = \pi(a)\pi(b)$  which means that  $\pi$  is a group homomorphism.

Suppose  $N \in \mathcal{G}$  satisfies  $e \in N$ . Then  $N = \pi(e)$  is the neutral element of  $\mathcal{G}$ . As

$$S = \pi^{-1}(\{S\}) = \pi^{-1}(\{\pi(a)\}) = a(\ker \pi) = (\ker \pi)a$$

and  $N = \pi^{-1}(\{N\}) = \ker \pi$  we conclude that  $S = aN = Na$ .

4. **(20 points)**

(a) **(5 pts)**  $e \in H$  as  $f(e) = e' = g(e)$ ; thus  $H \neq \emptyset$ . Let  $a, b \in H$ . The calculation

$$f(ab^{-1}) = f(a)f(b^{-1}) = f(a)f(b)^{-1} = g(a)g(b)^{-1} = g(a)g(b^{-1}) = g(ab^{-1})$$

shows that  $ab^{-1} \in H$ . Therefore  $H \leq G$ .

(b) **(5 pts)** *Only if.* Suppose  $f = g$ . Then  $f(a) = g(a)$  for all  $a \in G$ ; in particular  $f(s) = g(s)$  for all  $s \in S$ . *If.* Suppose that  $f(s) = g(s)$  for all  $s \in S$ . Then  $S \subseteq H$  and consequently  $\langle S \rangle \subseteq H$  since the latter is a subgroup of  $G$ . Therefore  $G = \langle S \rangle \subseteq H (\subseteq G)$  from which  $G = H$  follows. We have shown that  $f(a) = g(a)$  for all  $a \in G$ , or equivalently  $f = g$ .

(c) **(5 pts)** First of all suppose that  $S$  is any subset of  $G$  and  $a \in G$  satisfies  $sa = as$  for all  $s \in S$ . Then  $S \subseteq C_G(\{a\})$  which means  $\langle S \rangle \subseteq C_G(\{a\})$  since the latter is a subgroup of  $G$ .

Now let  $S, T$  be as in part (c) and let  $t \in T$ . Since  $st = ts$  for all  $s \in S$ ,  $H = \langle S \rangle \subseteq C_G(\{t\})$ . We have shown  $ht = th$  for all  $h \in H$ .

Now let  $h \in H$ . Then  $T \subseteq C_G(\{h\})$  and thus  $K = \langle T \rangle \subseteq C_G(\{h\})$ . Therefore  $hk = kh$  for all  $k \in K$ .

(d) **(5 pts)** By part (c)  $HK = KH$  and therefore  $HK \leq G$ . Let  $a, a' \in HK$ . Then  $a = hk$  and  $a' = h'k'$  for some  $h, h' \in H$  and  $k, k' \in K$ . Therefore

$$aa' = hkh'k' = hh'kk' = h'kk'hk = h'k'hk = a'a$$

which shows that  $HK$  is commutative.

5. **(25 points)** For  $a \in G$ , where  $G$  is a finite group, recall that the order of  $a$ , denoted  $|a|$ , is the least positive integer  $n$  satisfying  $a^n = e$  and  $|a| = |\langle a \rangle|$ .

(a) **(5 pts)**  $(ab)^m = a^m b^m = eb^m$ . Thus  $\langle b^m \rangle \subseteq \langle ab \rangle$ . Since  $\langle b^m \rangle = \langle b^{(m,n)} \rangle = \langle b \rangle$ , by Lagrange's Theorem  $m \mid |\langle ab \rangle|$ . Since  $ba = ab$  and  $(n, m) = 1$ , we conclude  $n \mid |\langle ab \rangle|$ . Thus  $mn \mid |\langle ab \rangle|$  since  $(m, n) = 1$ . The calculation  $(ab)^{mn} = a^{mn} b^{mn} = (a^m)^n (b^n)^m = e^n e^m = e$  shows that  $|\langle ab \rangle| \mid mn$ . Therefore  $mn = |\langle ab \rangle| = |ab|$ .

(b) **(5 pts)** The possible orders of elements of  $G$  are 1, 2, 3, or 6 since  $|G| = 6$ . We will show that  $x^2 = e$  for all  $x \in G$  or  $x^3 = e$  for all  $x \in G$  are not possible.

$x^2 = e$  for all  $x \in G$  is ruled out by Problem 2 since  $|G| \neq 2^n$  for all  $n \geq 0$ . Suppose  $x^3 = e$  for all  $x \in G$ . Then  $G$  has different subgroups  $H, K$  of order 3. Since  $H \cap K = H$  implies  $H \subseteq K$  and consequently  $H = K$ ,  $H \cap K \neq K$ . By Lagrange's Theorem  $H \cap K = (e)$ . Thus  $|G| \geq |HK| = |H||K|/|H \cap K| = 9 > |G|$ , a contradiction. Thus  $x^3 = e$  for all  $x \in G$  is ruled out.

Since  $|G| \neq 2^n$  for all  $n \geq 0$ , by Problem 2,  $a^2 \neq e$  for some  $a \in G$ . Thus  $G$  has an element of order 3 or 6. In the latter case  $G \simeq \mathbf{Z}_6$ . Thus we may assume that  $G$  has an element  $a$  of order 3.

Our conclusion: either  $G$  has an element of order 6 or elements  $a, b$  of orders 2 and 3 respectively. By part (a) the product  $ab$  has order 6. Thus  $G$  has an element of order 6 which means  $G \simeq \mathbf{Z}_6$ .

(c) **(5 pts)** Observe that  $Z(G) = (e)$  since  $G$  is non-abelian. Otherwise  $Z(G)$  has order 2 or 3 by Lagrange's Theorem. Since  $|G| = 6$ , by the same if  $L \leq G$  and  $Z(G) \subseteq L$  then  $L = Z(G)$  or  $L = G$ . Since  $G$  is not abelian there is a  $a \notin Z(G)$ . By Problem 4  $L = \langle a \rangle Z(G)$  is an abelian subgroup of  $G$  which properly contains  $Z(G)$ . Thus  $L = G$ , a contradiction. We have shown  $Z(G) = (e)$ .

The class equation reduces to  $6 = 1 + \ell 2 + m 3 + n 6$  for some  $\ell, m, n \geq 0$ . Therefore  $\ell = m = 1$  and  $n = 0$ .

(d) **(5 pts)** More generally, suppose that  $G$  is any group and  $H = \langle a \rangle \trianglelefteq G$  has 2 elements. Let  $g \in G$ . Then  $\{e, a\} = H = gHg^{-1} = \{geg^{-1}, gag^{-1}\} = \{e, gag^{-1}\}$  means  $gag^{-1} = a$ . Therefore  $a \in Z(G)$  which means  $H \subseteq Z(G)$ .

Since  $Z(G) = (e)$  for our particular  $G$ , which was shown for part (c),  $H$  is not normal.

(e) **(5 pts)** Note that  $\text{Ker } \pi \subseteq H$ . Since  $|H| = 2$  either  $\text{Ker } \pi = (e)$  or  $\text{ker } \pi = H$ . As  $\text{Ker } \pi$  is a normal subgroup of  $G$  and, by part (d),  $H$  is not,  $\text{Ker } \pi = (e)$ . Therefore  $\pi$  is injective and thus bijective since  $|G| = 6 = |S_A|$ .
