Localized Surface Plasmon Resonance (LSPR)

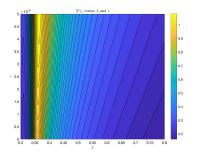

- The plasmon field is generated by the oscillation of electrons. This
 field in the metal is about 5 nm meaning that the surface plasmon
 does not penetrate deep into the metal.
- When light strikes the surface of a metal nanoparticle, if the electron cloud is excited at the resonance frequency, the light is absorbed more strongly. This case is called a resonance.
- When the dimension of the interface is much less than the surface plasmon propagation length (measured in μ m or mm), the surface plasmon is localized.

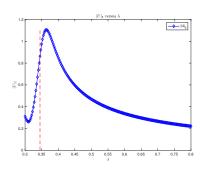

The figure is from *Metal nanoparticle photocatalysts: emerging processes for green organic synthesis.*

Localized Surface Plasmon Resonance

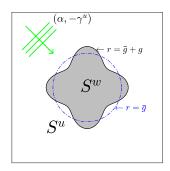

• There is an example showing that the resonance can be induced by selecting the appropriate light wavelength (frequency).

• The dashed red line represents the Fröhlich value of LSPR.

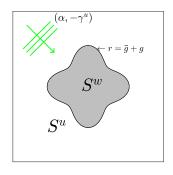

The Geometry

- We consider a y-invariant, doubly layered structure.
- Dielectrics occupy the unbounded exterior; a metal fills the bounded interior.
- The interface is described in polar coordinates by $r = \bar{g} + g(\theta)$.
- exterior domain $S^u := \{r > \bar{g} + g(\theta)\}$ interior domain $S^w := \{r < \bar{g} + g(\theta)\}$

3 / 30

Incident Radiation

- The structure is illuminated by monochromatic plane-wave incident radiation of frequency ω .
- Consider the reduced electric and magnetic fields

$$\mathbf{E}(r,\theta) = e^{i\omega t}\underline{\mathbf{E}}, \qquad \mathbf{H}(r,\theta) = e^{i\omega t}\underline{\mathbf{H}}.$$

- Incident, scattered, total fields are all 2π -periodic in θ .
- The scattered radiation is "outgoing" in S^u and bounded in S^w .

Xin Tong (UIC)

The Penetrable obstacle scattering problem

- In this 2D setting the time-harmonic Maxwell equations decouple into two scalar Helmholtz problems: Transverse electric (TE) and transverse magnetic (TM) polarizations.
- We define the invariant (y) directions of the scattered (electric or magnetic) fields by $\{u(r,\theta),w(r,\theta)\}$ in S^u and S^w , respectively.

We seek outgoing/bounded, 2π -periodic solutions of

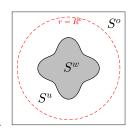

$$\begin{split} \Delta u + (k^u)^2 u &= 0, & r > \bar{g} + g(\theta), \\ \Delta w + (k^w)^2 w &= 0, & r < \bar{g} + g(\theta), \\ u - w &= -u^{\text{inc}} := \xi, & r &= \bar{g} + g(\theta), \\ \tau^u \partial_{\mathbf{N}} u - \tau^w \partial_{\mathbf{N}} w &= \tau^u (-\partial_{N} u^{\text{inc}}) := \tau^u \nu, & r &= \bar{g} + g(\theta), \end{split}$$

where $u^{\rm inc}$ is the incident radiation, and $\tau^u=\tau^w=1$ (TE) or $\{\tau^u=1/\epsilon^{(u)},\tau^w=1/\epsilon^{(w)}\}$ (TM).

Transparent Boundary Conditions

- Regarding the Outgoing Wave Condition (Sommerfeld Radiation Condition), we introduce an artificial boundary $\{r=R^o, R^o>\bar{g}+|g|_{L^\infty}\}$ and define the domain $S^o:=\{r>R^o\}$.
- The solution of Helmholtz problem on S^o with Dirichlet boundary data, say $u(R^o, \theta) = \underline{u}(\theta)$, is

$$u(r,\theta) = \sum_{p=-\infty}^{\infty} \underline{\hat{u}}_p \frac{H_p(k^u r)}{H_p(k^u R^o)} e^{ip\theta},$$

where H_p is the pth Hankel function of first kind.

• We compute the *outward–pointing* Neumann data at the artificial boundaries, and define the order-one Fourier multipliers $T^{(u)}$,

$$-\partial_{r}u(R^{o},\theta)=\sum_{p=-\infty}^{\infty}-k^{u}\underline{\hat{u}}_{p}\frac{H_{p}^{\prime}(k^{u}R^{o})}{H_{p}(k^{u}R^{o})}e^{ip\theta}=:T^{(u)}\left[\underline{u}(\theta)\right].$$

Then the periodic, outward propagating solutions to

$$\Delta u + (k^u)^2 u = 0, \quad r > \bar{g} + g(\theta),$$

equivalently solve

$$\Delta u + (k^u)^2 u = 0, \qquad \qquad \bar{g} + g(\theta) < r < R^o,$$

$$\partial_r u + T_u[u] = 0, \qquad \qquad r = R^o.$$

- Similarly, we choose another artificial boundary $\{r=R_i, \quad 0 < R_i < \bar{g} |g|_{L^{\infty}}\}$ which defines the domain $S_i := \{r < R_i\}$ and the Dirichlet data $\underline{w}(\theta)$.
- The order-one Fourier multiplier $T^{(w)}$ is

$$\partial_r w(R_i, \theta) = \sum_{p=-\infty}^{\infty} k^w \underline{\hat{w}}_p \frac{J_p'(k^w R_i)}{J_p(k^w R_i)} e^{ip\theta} =: T^{(w)} \left[\underline{w}(\theta)\right],$$

where J_p is the pth Bessel function of first kind.

A summary

The penetrable obstacle scattering problem is equivalent to solve

$$\Delta u + (k^{u})^{2} u = 0, \qquad r > \bar{g} + g(\theta),$$

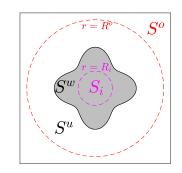

$$\Delta w + (k^{w})^{2} w = 0, \qquad r < \bar{g} + g(\theta),$$

$$u - w = \xi, \qquad r = \bar{g} + g(\theta),$$

$$\tau^{u} \partial_{\mathbf{N}} u - \tau^{w} \partial_{\mathbf{N}} w = \tau^{u} \nu, \qquad r = \bar{g} + g(\theta),$$

$$\partial_{r} u + T^{(u)} [u] = 0, \qquad r = R^{o},$$

$$\partial_{r} w - T^{(w)} [w] = 0, \qquad r = R_{i}.$$

Non-Overlapping Domain Decomposition Method

- The idea is thinking the solution layer by layer. What about the interface?
- Let the outer/inner Dirichlet traces and their (outward) Neumann counterparts be

$$U(\theta) := u(\bar{g} + g(\theta), \theta), \qquad \tilde{U}(\theta) := -(\partial_N u)(\bar{g} + g(\theta), \theta),$$

$$W(\theta) := w(\bar{g} + g(\theta), \theta), \qquad \tilde{W}(\theta) := (\partial_N w)(\bar{g} + g(\theta), \theta).$$

At the interface, we have

$$\begin{cases} u - w = \xi, \\ \tau^{u} \partial_{\mathbf{N}} u - \tau^{w} \partial_{\mathbf{N}} w = \tau^{u} \nu, \end{cases} \Rightarrow \begin{cases} U - W = \xi, \\ -\tau^{u} \tilde{U} - \tau^{w} \tilde{W} = \tau^{u} \nu. \end{cases}$$

Define the Dirichlet–Neumann Operators

$$G^{(u)}: U \to \tilde{U}, \ G^{(w)}: W \to \tilde{W}. \ \left(\Rightarrow \begin{cases} U - W = \xi, \\ -\tau^u G^{(u)}[U] - \tau^w G^{(w)}[W] = \tau^u \nu. \end{cases}\right)$$

Impedance-Impedance Operator (IIO)

 $\text{Motivation: apply the linear operator } P = \begin{pmatrix} Y & -\mathbb{1} \\ Z & -\mathbb{1} \end{pmatrix} \text{ to the BCs } \\ \begin{cases} u - w = \xi, \\ \tau^u \partial_{\mathbf{N}} u - \tau^w \partial_{\mathbf{N}} w = \tau^u \nu, \end{cases}$

$$\begin{array}{ll} \text{resulting} & & \left[-\tau^u \partial_N u + Y u \right] + \left[\tau^w \partial_N w - Y w \right] = \left[-\tau^u \nu + Y \xi \right] := \zeta, \\ \left[-\tau^u \partial_N u + Z u \right] + \left[\tau^w \partial_N w - Z w \right] = \left[-\tau^u \nu + Z \xi \right] := \psi. \end{array}$$

- The Y and Z are unequal operators to be specified. We choose $\pm i\eta$ for a constant $\eta \in \mathbb{R}^+$ later for numerical experiment.
- Let the outer/inner Impedance and their outer/inner counterparts be $I^u := [-\tau^u \partial_N u + Yu]_{r=\bar{\sigma}+\sigma}, \quad I^w := [\tau^w \partial_N w Zw]_{r=\bar{\sigma}+\sigma},$

$$\tilde{I}^u := [-\tau^u \partial_N u + Zu]_{r=\bar{g}+g} \,, \qquad \tilde{I}^w := [\tau^w \partial_N w - Yw]_{r=\bar{g}+g} \,.$$

Define the Impedance-Impedance Operators

$$Q:I^u\to \tilde{I}^u,\quad S:I^w\to \tilde{I}^w,$$

then write

$$\begin{cases} I^{u} + \tilde{I}^{w} = \zeta \\ \tilde{I}^{u} + I^{w} = \psi \end{cases} \Rightarrow \begin{pmatrix} \mathbb{1} & S \\ Q & \mathbb{1} \end{pmatrix} \begin{pmatrix} I^{u} \\ I^{w} \end{pmatrix} = \begin{pmatrix} \zeta \\ \psi \end{pmatrix}.$$

Definition 1 [Exterior Problem with DNO]: Given a sufficiently smooth deformation $g(\theta)$, the unique periodic solution of

$$\Delta u + (k^{u})^{2} u = 0, \qquad \qquad \bar{g} + g(\theta) < r < R^{\circ},$$

$$u(\bar{g} + g(\theta), \theta) = U, \qquad \qquad r = \bar{g} + g(\theta),$$

$$\partial_{r} u + T^{(u)}[u] = 0, \qquad \qquad r = R^{\circ},$$

defines the DNO

$$G^{(u)}[U] = G^{(u)}(R^o, \bar{g}, g)[U] := -(\partial_N u)(\bar{g} + g(\theta), \theta) = \tilde{U}.$$

Definition 2 [Interior Problem with DNO]: Given a sufficiently smooth deformation $g(\theta)$, if we are not at a Dirichlet eigenvalue of the Laplacian on $\{R_i < r < \bar{g} + g(\theta)\}$, the unique periodic solution of

$$\Delta w + (k^{w})^{2} w = 0, \qquad R_{i} < r < \bar{g} + g(\theta),$$

$$w(\bar{g} + g(\theta), \theta) = W, \qquad r = \bar{g} + g(\theta),$$

$$\partial_{r}w - T^{(w)}[w] = 0, \qquad r = R_{i},$$

defines the DNO

$$G^{(w)}[W] = G^{(w)}(R_i, \bar{g}, g)[W] := (\partial_N w)(\bar{g} + g(\theta), \theta) = \tilde{W}.$$

Xin Tong (UIC) LSPR July 7, 2019 11 / 30

Definition 3 [Exterior Problem with IIO]: Given a sufficiently smooth deformation $g(\theta)$, the unique periodic solution of

$$\Delta u + (k^{u})^{2} u = 0, \qquad \bar{g} + g(\theta) < r < R^{\circ},$$

$$-\tau^{u} \partial_{\mathbf{N}} u + Yu = I^{u}, \qquad r = \bar{g} + g(\theta),$$

$$\partial_{r} u + T^{(u)}[u] = 0, \qquad r = R^{\circ},$$

defines the IIO

$$Q[I^{u}] = Q(R^{o}, \bar{g}, g)[I^{u}] := -\tau^{u}\partial_{\mathbf{N}}u + Zu := \tilde{I}^{u}.$$

Definition 4 [Interior Problem with IIO]: Given a sufficiently smooth deformation $g(\theta)$, the unique periodic solution of

$$\Delta w + (k^{w})^{2} w = 0, \qquad R_{i} < r < \bar{g} + g(\theta),$$

$$\tau^{w} \partial_{\mathbf{N}} w - Zw = I^{w}, \qquad r = \bar{g} + g(\theta),$$

$$\partial_{r} w - T^{(w)}[w] = 0, \qquad r = R_{i},$$

defines the IIO

$$S[I^w] = S(R_i, \bar{g}, g)[I^w] := \tau^u \partial_{\mathbf{N}} w - Yw := \tilde{I}^w$$

Xin Tong (UIC) LSPR July 7, 2019 12 / 30

Numerical Methods

- Many numerical algorithms have been devised for the simulation of these problems, for instance, Finite Differences, Finite Elements, Spectral Elements.
- These methods suffer from the requirement that they discretize the full volume of the problem domain.
- Surface Methods, especially the High-Order Perturbation of Surfaces (HOPS) methods:
 - provide the solution at interface (we want)
 - only discretize the layer interfaces;
 - deliver high-accuracy simulations with greatly reduced operation counts.
- Foundational contributions:
 - Field Expansions: Bruno & Reitich (1993),
 - 2 Transformed Field Expansions: Nicholls & Reitich (1999).

Perturbation Expansions

- As with all HOPS schemes, the Method of Field Expansions (FE) begins with the $g(\theta) = \varepsilon f(\theta)$.
- Provided that f is sufficiently smooth, $\{Q,S\}$, and data, $\{\zeta,\psi\}$, can be shown to be analytic in ε so that the following Taylor series are strongly convergent

$$\{Q, S, \zeta, \psi, I^{u}, I^{w}\} = \{Q, S, \zeta, \psi, I^{u}, I^{w}\}(\varepsilon) = \sum_{n=0}^{\infty} \{Q_{n}, S_{n}, \zeta_{n}, \psi_{n}, I^{u}_{n}, I^{w}_{n}\}\varepsilon^{n}.$$

ullet It is straightforward to identify a recursive formula for $\{I_n^u,I_n^w\}$

$$\begin{pmatrix} \mathbb{1} & S_0 \\ Q_0 & \mathbb{1} \end{pmatrix} \begin{pmatrix} I_n^u \\ I_n^w \end{pmatrix} = \begin{pmatrix} \zeta_n \\ \psi_n \end{pmatrix} - \sum_{m=0}^{n-1} \begin{pmatrix} 0 & S_{n-m} \\ Q_{n-m} & 0 \end{pmatrix} \begin{pmatrix} I_m^u \\ I_m^w \end{pmatrix}, \quad \mathcal{O}(\varepsilon^n).$$

• We need $\{Q_0, S_0\}$ and $\{Q_m, S_m\}$, m = 1, ..., n - 1.

Method of Field Expansions

- Focusing upon the field u (outer domain), with $u = \sum_{n=0}^{\infty} u_n(r,\theta) \varepsilon^n$.
- Insert it into the Exterior Problem with IIO

$$\Delta u + (k^{u})^{2} u = 0, \qquad \bar{g} + g(\theta) < r < R^{\circ},$$

$$-\tau^{u} \partial_{\mathbf{N}} u + Yu = I^{u}, \qquad r = \bar{g} + g(\theta),$$

$$\partial_{r} u + T^{(u)}[u] = 0, \qquad r = R^{\circ},$$

• The u_n must be 2π -periodic, outward-propagating solutions of the elliptic boundary value problem

$$\Delta u_n + (k^u)^2 u_n = 0, \qquad \qquad \bar{g} < r < R^o,$$

$$-\tau^u \partial_{\mathbf{N}} u_n + Y u_n = I_n^u + \mathbf{L}_{n-1}, \qquad \qquad r = \bar{g},$$

$$\partial_r u_n + T^{(u)} [u_n] = 0, \qquad \qquad r = R^o,$$

ullet The exact solution is, with $\hat{u}_{n,p}$ determined by given data $I_n^u + L_{n-1}$

$$u_n(r,\theta) = \sum_{p=-\infty}^{\infty} \hat{u}_{n,p} \frac{H_p(k^u r)}{H_p(k^u \bar{g})} e^{ip\theta}.$$

Xin Tong (UIC) LSPR July 7, 2019 15 / 30

Method of Field Expansions

- Looking for $\{Q_0, S_0\}$ and $\{Q_m, S_m\}$, $m = 1, \dots n 1$.
- Recall that

$$\sum_{n=0}^{\infty} Q_n \varepsilon^n = Q[I^u] := -\tau^u (\partial_{\mathbf{N}} u) (\bar{g} + g(\theta), \theta) + (Zu) (\bar{g} + g(\theta), \theta)$$

$$u = \sum_{n=0}^{\infty} u_n(r, \theta) \varepsilon^n \quad \text{and} \quad u_n(r, \theta) = \sum_{p=-\infty}^{\infty} \hat{u}_{n,p} \frac{H_p(k^u r)}{H_p(k^u \bar{g})} e^{ip\theta}.$$

• The calculation involves expanding Hankel functions in power series in ε , equating like power of ε , and etc, which results in

$$\begin{split} Q_{0}[I^{u}] &= \sum_{p=-\infty}^{\infty} \hat{I_{p}^{u}} \frac{-(k^{u}\bar{g})\tau^{u}H_{p}'(k^{u}\bar{g}) + Z_{p}H_{p}(k^{u}\bar{g})}{-(k^{u}\bar{g})\tau^{u}H_{p}'(k^{u}\bar{g}) + Y_{p}H_{p}(k^{u}\bar{g})} e^{ip\theta} \\ Q_{n}[I^{u}] &= -\frac{f}{\bar{g}}Q_{n-1}(f)[I^{u}] + \mathsf{Terms}(u_{n}, u_{n-1}, \dots u_{0}, f) \end{split}$$

• Similarly, S_0 and S_m are computed by **Interior Problem with IIO**.

Method of Transformed Field Expansions

- The method of Transformed Field Expansions (TFE) proceeds a domain-flattening change of variables prior to perturbation expansion.
 We consider the Interior Problem with IIO.
- The change of variable is

$$r' = \frac{(\bar{g} - R_i)r + R_i g(\theta)}{\bar{g} + g(\theta) - R_i}, \quad \theta' = \theta,$$

which maps the perturbed domain $\{R_i < r < \bar{g} + g(\theta)\}$ to the separable one $\{R_i < r' < \bar{g}\}$.

• This transformation changes the field w (denoted by v) and modifies the problem to

$$\Delta v + (k^{w})^{2} v = F(r, \theta; g), \qquad R_{i} < r < \bar{g},$$

$$\tau^{w} \partial_{\mathbf{N}} v - Zv = I^{w}, \qquad r = \bar{g},$$

$$\partial_{r} v - T^{(w)}[v] = K(\theta; g), \qquad r = R_{i}.$$

• The Gerlakin methods is applied to solve the non-homogeneous BVP.

Xin Tong (UIC) LSPR July 7, 2019 17 / 30

Validation by the Method of Manufactured Solutions

• We consider 2π -periodic, outgoing solutions of the Helmholtz equation, and the bounded counterpart

$$u^q(r,\theta) = A_u^q H_q(k^u r) e^{iq\theta}, \ w^q(r,\theta) = A_w^q J_q(k^w r) e^{iq\theta}, \ q \in \mathbf{Z}, \quad A_u^q, A_w^q \in \mathbf{C}.$$

ullet For a given choice of f=f(heta) we compute, the exact interior Neumann data and the exact interior Impedance data

$$\rho^{\mathsf{in}}(\theta) := [\partial_{N} w^{q}]_{r = \bar{\mathbf{g}} + \varepsilon f(\theta)} = \tilde{W}(\theta),$$

$$\phi^{\mathsf{in}}(\theta) := [\tau^{u} \partial_{N} w^{q} - Yw^{q}]_{r = \bar{\mathbf{g}} + \varepsilon f(\theta)} = \tilde{I}^{w}(\theta).$$

• We approximate $\{u, w\}$ by

$$u^{N_{\theta},N}(r,\theta) := \sum_{n=0}^{N} \sum_{p=-N_{\theta}/2}^{N_{\theta}/2-1} \hat{u}_{n,p} e^{ip\theta} \varepsilon^{n}, \quad w^{N_{\theta},N}(r,\theta) := \sum_{n=0}^{N} \sum_{p=-N_{\theta}/2}^{N_{\theta}/2-1} \hat{w}_{n,p} e^{ip\theta} \varepsilon^{n}.$$

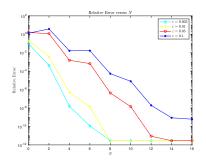

Xin Tong (UIC) LSPR July 7, 2019 18 / 30

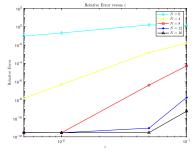

DNO versus IIO

- We select the 2π -periodic and analytic function $f(\theta) = e^{\cos(\theta)}$
- Set the parameters:

$$q = 2$$
, $A_u^q = 2$, $A_w^q = 1$, $N_\theta = 64$, $N = 16$.

- The operators are Y = 3.4i, Z = -3.4i.
- To begin with our study, with the choice $\bar{g} = 0.5$, we carry out simulations with IIO formulation.

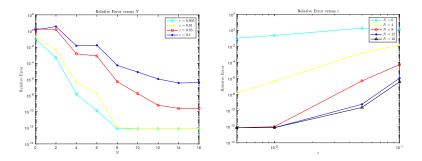

Xin Tong (UIC)

DNO versus IIO

We repeat this with our DNO approch,

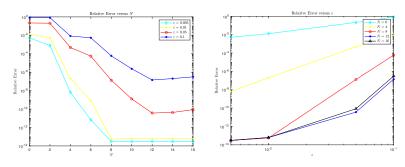

• In this non-resonant configuration ($\bar{g}=0.5$), both algorithms display a spectral rate of convergence as N is refined (improving as ε is decreased).

Xin Tong (UIC) LSPR July 7, 2019 20 / 30

DNO versus IIO: a nearly-resonant configuration

- We note that the choice of $\bar{g}=1$ will induce a singularity in the interior DNO $G^{(w)}$.
- To test the performance, we select $\bar{g} = 1 10^{-12}$.
- The IIO algorithm shows

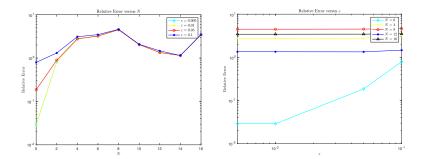

21 / 30

Xin Tong (UIC) LSPR July 7, 2019

DNO versus IIO: a nearly-resonant configuration

• The DNO algorithm shows

 In this nearly resonant configuration, while IIO algorithm displays a spectral rate of convergence as N is refined, the DNO approach does not provide results of the same quality.

 Xin Tong
 (UIC)
 LSPR

DNO versus IIO: a resonant configuration

- Last, we select $\bar{g} = 1 10^{-16}$ (to machine precision).
- The IIO algorithm shows

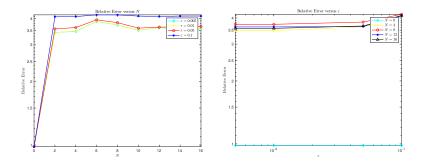

Xin Tong (UIC)

23 / 30

DNO versus IIO: a resonant configuration

The DNO algorithm shows

• In this resonant configuration, the IIO algorithm again displays a spectral rate of convergence as *N* is refined, while the DNO approach delivers completely unacceptable results.

Xin Tong (UIC) LSPR July 7, 2019 24 / 30

Analyticity of Solutions via IIOs

Rewrite the boundary conditions compactly as $\mathbf{AV} = \mathbf{R}$

$$\underbrace{\begin{pmatrix} \mathbb{1} & S \\ Q & \mathbb{1} \end{pmatrix}}_{\mathbf{A}} \underbrace{\begin{pmatrix} \mathbf{I}^u \\ \mathbf{I}^w \end{pmatrix}}_{\mathbf{V}} = \underbrace{\begin{pmatrix} \zeta \\ \psi \end{pmatrix}}_{\mathbf{R}}.$$

• We can show, the IIOs, Q and S, are analytic in the perturbation parameter ε so that the following expansions are strongly convergent in an appropriate Sobolev space

$$Q(\varepsilon f) = \sum_{n=0}^{\infty} Q_n(f)\varepsilon^n, \quad S(\varepsilon f) = \sum_{n=0}^{\infty} S_n(f)\varepsilon^n.$$

• Next we can show the operator ${\bf A},$ the data ${\bf R},$ and solution ${\bf V},$ are analytic under certain conditions $~_{\infty}$

$$\{\mathbf{A}(\varepsilon f), \mathbf{V}(\varepsilon f), \mathbf{R}(\varepsilon f)\} = \sum_{n=0} \{\mathbf{A}_n(f), \mathbf{V}_n(f), \mathbf{R}_n(f)\} \varepsilon^n.$$

• Furthermore, the \mathbf{V}_n must satisfy $^{n=0}$

$$\mathbf{V}_n = \mathbf{A}_0^{-1} \left\{ \mathbf{R}_0 - \sum_{\ell=0}^{n-1} \mathbf{A}_{n-\ell} \mathbf{V}_\ell \right\},$$

\(\ell \) \(\el

Analyticity: the Main Theorem [Nicholls17]

Given two Banach spaces $X = Y = H^{-1/2} \times H^{-1/2}$, suppose that:

H1 $\mathbf{R}_n \in Y$ for all $n \ge 0$, and there exist $C_R > 0$, $B_R > 0$ such that $\|\mathbf{R}_n\|_Y \le C_R B_R^n$, $n \ge 0$.

- **H2** $\mathbf{A}_n: X \to Y$ for all $n \ge 0$, and there exist $C_A > 0$, $B_A > 0$ such that $\|\mathbf{A}_n\|_{X \to Y} \le C_A B_A^n$, $n \ge 0$.
- **H3** $\mathbf{A}_0^{-1}: Y \to X$, and there exists a constant $C_e > 0$ such that

$$\left\|\mathbf{A}_0^{-1}\right\|_{Y\to X}\leq C_e.$$

Then the equation $\mathbf{AV} = \mathbf{R}$ has a unique solution, and there exist constants $C_V > 0$ and $B_V > 0$ such that

$$\|\mathbf{V}_n\|_X \le C_V B_V^n, \quad n \ge 0,$$

for any $C_V \ge 2C_eC_R$, $B_V \ge \max\{B_R, 2B_A, 4C_eC_AB_A\}$,

which implies that, $\sum \mathbf{V}_n \varepsilon^n$ converges for all ε such that $0 \le B_V \varepsilon < 1$.

Sketch of the proof

Hypothesis H1: the **R** is estimated using the given data (incident radiation)

$$\mathbf{R}_{n} = \begin{pmatrix} \zeta_{n} \\ \psi_{n} \end{pmatrix} = \begin{pmatrix} \tau^{u} \nu_{n} + Y \xi_{n} \\ -\tau^{u} \nu_{n} + Z \xi_{n} \end{pmatrix}.$$

Hypothesis H3: the existence and invertibility properties of the operator \mathbf{A}_0 are equivalent to the existence and uniqueness properties of the solution to

$$\begin{pmatrix} \mathbb{1} & S_0 \\ Q_0 & \mathbb{1} \end{pmatrix} \begin{pmatrix} I^u \\ I^w \end{pmatrix} = \begin{pmatrix} \zeta \\ \psi \end{pmatrix},$$

where

$$\mathbf{A}_0 = \begin{pmatrix} \mathbb{1} & S_0 \\ Q_0 & \mathbb{1} \end{pmatrix}.$$

Sketch of the proof

Hypothesis H2: the estimates for $\mathbf{A}_n = \begin{pmatrix} 0 & S_n \\ Q_n & 0 \end{pmatrix}$ are equivalent to the analyticity of the IIOs, i.e.

$$||Q_n[I^u]||_{H^{-1/2}} \le C_Q B_Q^n, \quad ||S_n[I^w]||_{H^{-1/2}} \le C_S B_S^n.$$

For instance, the analyticity of S is stated in the following.

Applying TFE to the interior problem results in an elliptic BVP

$$\begin{split} \Delta v_n + (k^w)^2 v_n &= F_n, & R_i < r < \bar{g}, \\ \partial_r v_n - \frac{Z}{\tau^w \bar{g}} v_n &= \frac{\delta_{n,0} I^w}{\tau^w \bar{g}} + I_n, & r &= \bar{g}, \\ \partial_r v_n - T^{(w)} [v_n] &= h_n, & r &= R_i. \end{split}$$

Elliptic estimate shows that

$$\|v_n\|_{H^1} \le \|F_n\|_{(H^1)'} + \|\delta_{n,0}I^w\|_{H^{-1/2}} + \|I_n\|_{H^{-1/2}} + \|h_n\|_{H^{-1/2}}.$$

- **3** Estimate the non-homogeneous terms F_n , $\delta_{n,0}I^w$, I_n , h_n .
- Estimate S_n by $S_n[I^w] \approx S_{n-1}[I^w] + S_{n-2}[I^w] + \text{Terms}(v_n, v_{n-1}, v_{n-2})$.

Conclusion

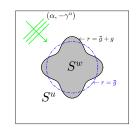

We seek outgoing/bounded, 2π -periodic solutions of the penetrable obstacle scattering problem

$$\Delta u + (k^{u})^{2} u = 0, \qquad r > \bar{g} + g(\theta),$$

$$\Delta w + (k^{w})^{2} w = 0, \qquad r < \bar{g} + g(\theta),$$

$$u - w = -u^{\text{inc}} \qquad r = \bar{g} + g(\theta),$$

$$\tau^{u} \partial_{N} u - \tau^{w} \partial_{N} w = \tau^{u} (-\partial_{N} u^{\text{inc}}), \quad r = \bar{g} + g(\theta),$$

- The algorithms
 - via DNO using FE and TFE
 - via IIO using FE and TFE
- 2 The numerical experiments
 - convergence study
 - comparison between DNO and IIO
 - simulation of nanorods (LSPRs)
- The analyticity via IIO
