problem statement

The problem:

Solve a polynomial system on a computer with multicore processors.

- What does solve mean?
 - compute a numerical irreducible decomposition,
 - in blackbox mode: fixed algorithms, tolerances, and parameters.
- What type of shared memory parallelism?
 - pipelining to interlace root counting with path tracking,
 - multithreading: apply dynamic load balancing to path trackers.

Focus on one benchmark: the cyclic *n*-roots problems, n = 12.

Free and Open Source Software: QDlib, MixedVol, DEMiCs, PHCpack. https://github.com/janverschelde/phcpack

Extend blackbox solver in PHCpack: phc -B -tp, with p threads. phc -B -t88 cyclic12 cyclic12.out

the cyclic 4-roots system

what is a polynomial system?

The equations for the cyclic 4-roots problem are

$$\mathbf{f}(\mathbf{x}) = \begin{cases} x_1 + x_2 + x_3 + x_4 = 0\\ x_1 x_2 + x_2 x_3 + x_3 x_4 + x_4 x_1 = 0\\ x_1 x_2 x_3 + x_2 x_3 x_4 + x_3 x_4 x_1 + x_4 x_1 x_2 = 0\\ x_1 x_2 x_3 x_4 - 1 = 0. \end{cases}$$

This system has two solution curves of degree two. There are no isolated solutions. Our focus is on n = 8, 9, 12.

Lemma (Backelin's Lemma)

If n has a quadratic divisor, $n = \ell k^2$, $\ell < k$, then there are (k - 1)-dimensional cyclic n-roots.

H. Führ and Z. Rzeszotnik: **On biunimodular vectors of unitary matrices.** *Linear Algebra and its Applications* 484: 86–129, 2015.

D N 4 B N 4 B N 4 B

the embedded cyclic 4-roots system how to represent solution curves?

To compute *generic points* on the solution curves, the system is augmented by one linear equation and one slack variable z_1 .

$$E_{1}(\mathbf{f}(\mathbf{x}), z_{1}) = \begin{cases} x_{1} + x_{2} + x_{3} + x_{4} + \gamma_{1} z_{1} = 0\\ x_{1} x_{2} + x_{2} x_{3} + x_{3} x_{4} + x_{4} x_{1} + \gamma_{2} z_{1} = 0\\ x_{1} x_{2} x_{3} + x_{2} x_{3} x_{4} + x_{3} x_{4} x_{1} + x_{4} x_{1} x_{2} + \gamma_{3} z_{1} = 0\\ x_{1} x_{2} x_{3} x_{4} - 1 + \gamma_{4} z_{1} = 0\\ c_{0} + c_{1} x_{1} + c_{2} x_{2} + c_{3} x_{3} + c_{4} x_{4} + z_{1} = 0. \end{cases}$$

The constants γ_1 , γ_2 , γ_3 , γ_4 and c_0 , c_1 , c_2 , c_3 , c_4 are randomly generated complex numbers.

The 4 solutions with $z_1 = 0$ are *generic points* on the solution curves.

polyhedral homotopies in parallel

Polyhedral homotopies solve *sparse* polynomial systems.

- The mixed volume provides a generically sharp root count.
- 2 Polyhedral homotopies track as many paths as the mixed volume.

The Bézout bound for the cyclic 12-roots problem is 479,001,600. A linear-product bound lowers this to 342,875,319. The mixed volume of the cyclic 12-roots system equals 500,352.

イロト イポト イラト イラト

a 2-stage pipeline

The input to the pipeline is a random coefficient system $\mathbf{g}(\mathbf{x}) = \mathbf{0}$ and the output are its solutions in the set $\mathbf{g}^{-1}(\mathbf{0})$.

A 2-stage pipeline:

- thread P₀ computes the cells which define paths; and
- 2 p-1 threads $P_1, P_2, \ldots, P_{p-1}$ track paths to solve $\mathbf{g}(\mathbf{x}) = \mathbf{0}$.

< 口 > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

a space time diagram

Suppose the subdivision of the Newton polytopes has six cells. For regularity, assume

- producing one cell takes one time unit; and
- solving a start system takes 3 time units.

A space time diagram for a 2-stage pipeline:

- one thread produces 6 cells C_1, C_2, \ldots, C_6 ; and
- **2** 3 threads solve 6 start systems S_1, S_2, \ldots, S_6 .

The total time equals 9 units. It takes 24 time units sequentially. This pipeline with 4 threads gives a speedup of $24/9 \approx 2.67$.

speedup

Consider a scenario with *p* threads:

- the first thread produces *n* cells; and
- the other p 1 threads track all paths corresponding to the cells.

Assume that tracking all paths for one cell costs *F* times the amount of time it takes to produce that one cell.

The sequential time T_1 , parallel time T_p , and speedup S_p are

$$T_1 = n + Fn$$
, $T_p = p - 1 + \frac{Fn}{p - 1}$, $S_p = \frac{T_1}{T_p} = \frac{n(1 + F)}{p - 1 + \frac{Fn}{p - 1}}$.

The *pipeline latency* is p - 1, the time to fill up the pipeline with jobs.

Theorem

If
$$F = p - 1$$
, then $S_p = p$ for $n \to \infty$.

dynamic enumeration for mixed cells

DEMiCs of T. Mizutani and A. Takeda computes all mixed cells in a greedy manner, at a faster pace than MixedVol.

Times of the pipelined polyhedral homotopies with DEMiCs, on the embedded cyclic 12-roots system, 983,952 paths, for increasing values 2, 4, 8, 16, 32, 64 of tasks p.

р	seconds	=	hms format	speedup
2	56614	=	15h43m34s	1.00
4	21224	=	5h53m44s	2.67
8	9182	=	2h23m44s	6.17
16	4627	=	1h17m07s	12.24
32	2171	=	36m11s	26.08
64	1989	=	33m09s	28.46

The last time is an average over 13 runs. With 64 threads the times ranged between 23 minutes and 47 minutes.

an example

Consider the following system:

$$\mathbf{f}(\mathbf{x}) = \begin{cases} (x_1 - 1)(x_1 - 2)(x_1 - 3)(x_1 - 4) = 0\\ (x_1 - 1)(x_2 - 1)(x_2 - 2)(x_2 - 3) = 0\\ (x_1 - 1)(x_1 - 2)(x_3 - 1)(x_3 - 2) = 0\\ (x_1 - 1)(x_2 - 1)(x_3 - 1)(x_4 - 1) = 0. \end{cases}$$

In its factored form, the numerical irreducible decomposition shows:

(1) The three dimensional solution set is defined by $x_1 = 1$.

So For
$$x_1 = 2$$
, $x_2 = 1$ defines a two dimensional solution set.

There are twelve lines:

$$(2, 2, x_3, 1), (2, 2, 1, x_4), (2, 3, 1, x_4), (2, 3, x_3, 1),$$

$$\begin{array}{l} (3,1,1,x_4), (3,1,2,x_4), (3,2,1,x_4), (3,3,1,x_4), \\ (4,1,1,x_4), (4,1,2,x_4), (4,2,1,x_4), (4,3,1,x_4). \end{array}$$

4 isolated points: (3,2,2,1), (3,3,2,1), (4,3,2,1), (4,2,2,1).

不同 いんきいんき

the top dimensional system

Because the top dimension is three, three random hyperplanes and three slack variables z_1 , z_2 , z_3 are added:

$$\begin{cases} (x_1 - 1)(x_1 - 2)(x_1 - 3)(x_1 - 4) + \gamma_{1,1}z_1 + \gamma_{1,2}z_2 + \gamma_{1,3}z_3 = 0\\ (x_1 - 1)(x_2 - 1)(x_2 - 2)(x_2 - 3) + \gamma_{2,1}z_1 + \gamma_{2,2}z_2 + \gamma_{2,3}z_3 = 0\\ (x_1 - 1)(x_1 - 2)(x_3 - 1)(x_3 - 2) + \gamma_{3,1}z_1 + \gamma_{3,2}z_2 + \gamma_{3,3}z_3 = 0\\ (x_1 - 1)(x_2 - 1)(x_3 - 1)(x_4 - 1) + \gamma_{4,1}z_1 + \gamma_{4,2}z_2 + \gamma_{4,3}z_3 = 0\\ c_{1,1}x_1 + c_{1,2}x_2 + c_{1,3}x_3 + c_{1,4} + z_1 = 0\\ c_{2,1}x_1 + c_{2,2}x_2 + c_{2,3}x_3 + c_{2,4} + z_2 = 0\\ c_{3,1}x_1 + c_{3,2}x_2 + c_{3,3}x_3 + c_{3,4} + z_3 = 0 \end{cases}$$

Solving this system will give one generic point on $x_1 = 1$ and start solutions for the lower dimensional solution sets.

speedup

Assume that every path requires the same amount of time.

Theorem

Let T_p be the time it takes to track n paths with p threads. Then, the optimal speedup S_p is

$$S_p = p - \frac{p-r}{T_p}, \quad r = n \mod p.$$

If n < p, then $S_p = n$.

Corollary

Let T_p be the time it takes to track with p threads a sequence of n_0 , n_1 , ..., n_D paths. Then, the optimal speedup S_p is

$$S_p = p - \frac{dp - r_0 - r_1 - \dots - r_D}{T_p}, \quad r_k = n_k \mod p, k = 0, 1, \dots D.$$

homotopy membership tests

The solution line $x_1 = 1$ is represented by a generic point. The isolated solution is the point (2,0).

A homotopy membership verifies (2,0) does not belong to the line.

$$\mathbf{h}(\mathbf{x}, z_1, t) = \begin{cases} (x_1 - 1)(x_1 - 2) + \gamma_1 z_1 &= 0\\ (x_1 - 1)x_2^2 + \gamma_2 z_1 &= 0\\ (1 - t)c_0 + tc_3 + c_1x_1 + c_2x_2 + z_1 &= 0. \end{cases}$$

For t = 0, the constant c_0 is so that (2, 0) satisfies the last equation.

Tracking the path starting at (2, 0, 0) computes another generic point on $x_1 = 1$ if (2, 0) would lie on the solution line $x_1 = 1$.

testing singular candidate isolated points

Jan Verschelde (UIC)

Parallel Polynomial Homotopy Continuation

ICIAM 2019, 17 July 20/28

cascades of homotopy membership filters

Points on higher dimensional solution sets are removed.

On the example, we have one linear 3-dimensional set, one linear 2-dimensional set, 12 lines, and 4 isolated points.

The numbers at the right equal the number of paths in each stage.

speedup

Corollary

Let T_p be the time it takes to filter n_D , n_{D-1} , ..., $n_{\ell+1}$ singular points on components respectively of dimensions D, D - 1, ..., $\ell + 1$ and degrees d_D , d_{D-1} , ..., $d_{\ell+1}$. Then, the optimal speedup is

$$S_p = p - rac{(D-\ell)p - r_D - r_{D-1} - \cdots - r_{\ell+1}}{T_p}, \quad r_k = (n_k d_k) \mod p,$$

for $k = \ell + 1, \dots, D - 1, D$.

There are two reasons for a reduced parallelism:

- The number of singular solutions and the degrees of the solution sets could be smaller than the number of available cores.
- 2 To filter the output of the cascade, there are D(D + 1)/2 stages, so longer sequences of homotopies are considered.

Parallel Polynomial Homotopy Continuation

Polynomial Homotopy Continuation

2 A Parallel Numerical Irreducible Decomposition

Computational Experiments

- solving the cyclic 8- and cyclic 9-roots systems
- solving the cyclic 12-roots system

solving cyclic 8- and cyclic 9-roots systems

Both cyclic 8 and cyclic 9-roots are relatively small problems. Wall clock times in seconds with phc -B -tp for p threads:

	cyclic 8	3-roots	cyclic 9-roots		
р	seconds	speedup	seconds	speedup	
1	181.765	1.00	2598.435	1.00	
2	167.871	1.08	1779.939	1.46	
4	89.713	2.03	901.424	2.88	
8	47.644	3.82	427.800	6.07	
16	32.215	5.65	267.838	9.70	
32	22.182	8.19	153.353	16.94	
64	20.103	9.04	150.734	17.24	

With 64 threads, we can solve the cyclic 9-roots problem faster than solving the cyclic 8-roots problem on one thread.

running in double double and quad double precision

Double double and quad double arithmetic are implemented in QDlib, a software library by Y. Hida, X. S. Li, and D. H. Bailey, 2001.

In double precision, with 64 threads, the time

- for cyclic 8-roots reduces from 3 minutes to 20 seconds and
- for cyclic 9-roots from 43 minutes to 2 minutes and 30 seconds.

The wall clock times below are with 64 threads in higher precision.

	cyc	-roots	cyclic 9-roots			
	seconds	seconds = hms format		seconds =		hms format
dd	53.042	=	53s	498.805	=	8m19s
qd	916.020	=	15m16s	4761.258	=	1h19m21s

With 64 threads, we can compensate for the computational overhead caused by double double precision and achieve *quality up*.

-

solving the cyclic 12-roots system in parallel

The wall clock time on the blackbox solver on one thread is about 95 hours (almost 4 days), which includes the linear-product bound. The time reduces from 4 days to less than 3 hours with 64 threads:

	solving top system			casca	de and f	grand		
р	start	contin	total	cascade	filter	total	total	speedup
2	62813	47667	110803	44383	2331	46714	157518	1.00
4	21181	25105	46617	24913	1558	26471	73089	2.16
8	8933	14632	23896	13542	946	14488	38384	4.10
16	4656	7178	12129	6853	676	7529	19657	8.01
32	4200	3663	8094	3415	645	4060	12154	12.96
64	4422	2240	7003	2228	557	2805	9808	16.06

The solving of the top dimensional system breaks up in two stages:

- the solving of a start system (start) and the
- continuation to the solutions of the top dimensional system (contin).

Speedups are good in the cascade, but the filtering contains the factorization in irreducible components, which does not run in parallel.

running in double double precision

A run in double double precision with 64 threads ends after 7 hours and 37 minutes.

This time lies between the times in double precision

- with 8 threads, 10 hours and 39 minutes, and
- with 16 threads, 5 hours and 27 minutes.

Confusing quality with precision, from 8 to 64 threads, the working precision can be doubled,

with a reduction in time by 3 hours, from 10.5 hours to 7.5 hours.

conclusions

A numerical irreducible decomposition for the cyclic 12-roots system can be computed in less than 3 hours with 64 threads,

- using pipelining to solve the top dimensional system,
- with multitasking for the cascade and filtering stages.

In double double precision, it takes 7.5 hours with 64 threads.
